# Chapter 1

## Analysis

### 1.1 Background

Mr Myslov is a teacher at Tonbridge School, and currently runs the school chess club. Seldomly, a field day event will be held, in which the club convenes together, playing a chess, or another variant, tournament. This year, Mr Myslov has decided to instead, hold a tournament around another board game, namely laser chess, providing a deviation yet retaining the same familiarity of chess. However, multiple physical sets of laser chess have to be purchased for the entire club to play simultaneously, which is difficult due to it no longer being manufactured. Thus, I have proposed a solution by creating a digital version of the game.

#### 1.1.1 Game Description

Laser Chess is an abstract strategy game played between two opponents. The game differs from regular chess, involving a 10x8 playing board arranged in a predefined condition. The aim of the game is to position your pieces such that your laser beam strikes the opponents Pharoah (the equivalent of a king). Pieces include:

1. Pharoah
  - Equivalent to the king in chess
2. Scarab
  - 2 for each colour
  - Contains dual-sided mirrors, capable of reflecting a laser from any direction
  - Can move into an occupied adjacent square, by swapping positions with the piece on it (even with an opponent's piece)
3. Pyramid
  - 7 for each colour
  - Contains a diagonal mirror used to direct the laser
  - The other 3 out of 4 sides are vulnerable from being hit
4. Anubis

- 2 for each colour
- Large pillar with one mirrored side, vulnerable from the other sides

### 5. Sphinx

- 1 for each colour
- Piece from which the laser is shot from
- Cannot be moved

On each turn, a player may move a piece one square in any direction (similar to the king in regular chess), or rotate a piece clockwise or anticlockwise by 90 degrees. After their move, the laser will automatically be fired. It should be noted that a player's own pieces can also be hit by their own laser. As in chess, a three-fold repetition results in a draw. Players may also choose to forfeit or offer a draw.

#### 1.1.2 Current Solutions

Current free implementations of laser chess that are playable online are limited, seemingly only available on <https://laser-chess.com/>.

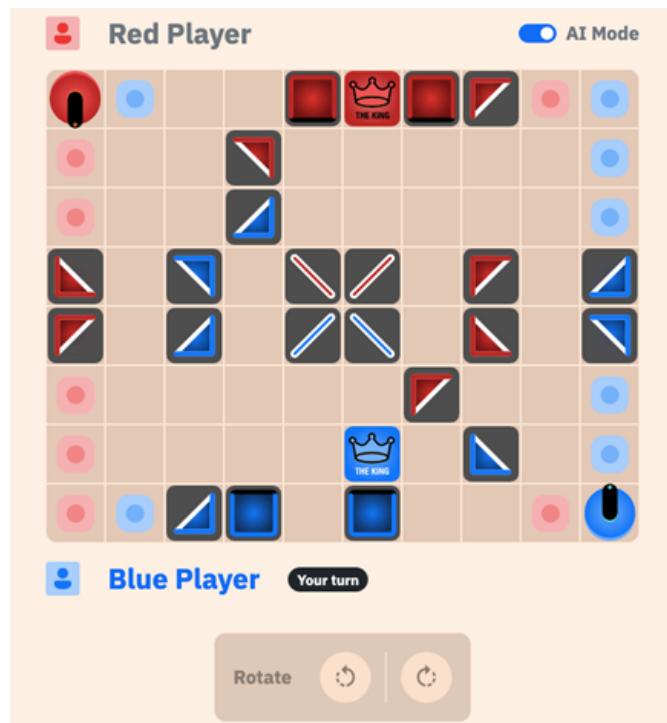

Figure 1.1: Online implementation on laser-chess.com

The game is hosted online and is responsive and visually appealing, with pieces easy to differentiate and displaying their functionality clearly. It also contains a two-player mode for playing between friends, or an option to play against a functional CPU bot. However, the game lacks the following basic functionalities that makes it unsuitable for my client's requests:

- No replay options (going through past moves)
  - A feature to look through previous moves is common in digital board game implementations
  - My client requires this feature as it is an essential tool for learning from past games and to aid in analysing past games
- No option to save and load previous games
  - This QOL feature allows games to be continued on if they cannot be finished in one sitting, and to keep an archive of past games
- Internet connection required
  - My client has specifically requested an offline version as the game will predominantly be played in settings where a connection might not be available (i.e. on a plane or the maths dungeons)
- Unable to change board configuration
  - Most versions of laser chess (i.e. Khet) contain different starting board configurations, each offering a different style of play

Our design will aim to append the missing feature from this website while learning from their commendable UI design.

### 1.1.3 Client Interview

**Q:** Why have you chosen Laser Chess as your request?

**A:** Everyone is familiar with chess, so choosing a game that feels similar, and requires the same thinking process and calculations was important to me. Laser chess fit the requirements, but also provides a different experience in that the new way pieces behave have to be learnt and adapted to. It hopefully will be more fun and a better fit for the boys than other variants such as Othello, as the laser aspects and visuals will keep it stimulating.

*Objectives 1 & 7*

Implementing laser chess in a style similar to normal chess will be important. The client also requests for it to be stimulating, requiring both proper gameplay and custom visuals.

---

**Q:** Have you explored any alternatives?

**A:** I remember Laser Chess was pretty popular years ago, but now it's harder to find a good implementation I can use, since I don't plan on buying multiple physical copies or paid online copies for every student. I have seen a few free websites offering a decent option, but I'm worried that with the terrible connection in the basement will prove unreliable if everybody tries to connect at once. However, I did find the ease-of-use and simple visuals of some websites pleasing, and something that I wish for in the final product as well.

*Objective 6*

The client's limitations call for a digital implementation that plays offline. Taking inspiration from alternatives, a user-friendly GUI is also expected.

---

**Q:** What features are you looking for in the final product?

**A:** I'm looking for most features chess websites like Chess.com or Lichess offer, a smooth playing experience with no noticeable bugs. I'm also expecting other features such as having a functional timer, being able to draw and resign, as these are important considerations in our everyday chess games too. Since this will be a digital game, I think having handy features such as indicators for moves and audio cues will also make it more user-friendly and enjoyable. If not for myself, having the option to play against a computer bot will be appreciated as well, since I'll be able to play during lesson time, or in the case of odd numbers in the tournament. All in all, I'd be happy with a final product that plays Laser Chess, but emulates the playing experience of any chess website well.

*Objectives 1 & 3 & 5*

Gameplay similar to that of popular chess websites is important to our client, introducing the requirement of subtle features such as move highlighting. A CPU bot is also important to our client, who enjoys thinking deeply and analysing chess games, and so will prove important both as a learning tool and as an opponent.

---

**Q:** Are there any additional features that might be helpful for your tournament use-cases?

**A:** Being able to configure the gameplay will be useful for setting custom time-controls for everybody. I also would like to archive games and share everybody's matches with the team, so having the functionality to save games, and to go through previous ones, will be highly requested too. Being able to quickly setup board starting positions or share them will also be useful, as this will allow more variety into the tournament and give the stronger players some more interesting options.

*Objectives 2 & 4*

Saving games and customising them is a big logistical priority for a tournament, as this will provide the means to record games and for opponents to all agree on the starting conditions, depending on the circumstances of the tournament.

## 1.2 Objectives

### 1.2.1 Client Objectives

The following objectives should be met to satisfy my clients' requirements:

1. All laser chess game logic should be properly implemented
  - (a) Pieces should be destroyed when laser hits their vulnerable side
  - (b) Pyramid should rotate laser by 90° from one side
  - (c) Scarab should rotate laser by 90° from both sides
  - (d) Anubis should absorb laser from one side
  - (e) Active colour should alternate every move
  - (f) Laser should automatically fire from the sphinx after a player move
  - (g) Travel path of laser should be correctly implemented
  - (h) Game should end when a player's pharaoh is destroyed
  - (i) Game should end in a draw if three-fold repetition is automatically detected
2. Game should process user input correctly

- (a) Clicking on a piece of the active colour selects it
  - (b) Clicking on an invalid square deselects the piece
  - (c) Clicking on a piece and an available square should move the piece
  - (d) Grabbing a piece and releasing it on an available square should move the piece
  - (e) Clicking on the clockwise or anticlockwise button should rotate the selected piece accordingly the piece
3. Save or load game options should be implemented
    - (a) Games should be encoded into FEN string format
    - (b) Games can be saved locally into external files
    - (c) Entering the browser screen should display all previous games
    - (d) Previous games should be sorted according to specific criteria (i.e. winner)
    - (e) User should be able to delete previous games
    - (f) User should be able to review previous games
    - (g) The review screen should display information relevant for each game
    - (h) Clicking on the previous or next buttons should scroll through moves
  4. Other board game requirements should be implemented
    - (a) Draws should be made an option
    - (b) Resigning should be made an option
    - (c) Timer displaying time left for each player should be displayed
    - (d) Time logic should be implemented, pausing when it is the opponent's turn, forfeiting players who run out of time
  5. Game settings and config should be customisable
    - (a) User should be able to play against another player or CPU
    - (b) User should be able to customise timer and duration
    - (c) User should be able to select starting colours
    - (d) User should be able to enter custom FEN string in the config screen
    - (e) Config screen should be able to detect invalid FEN strings
    - (f) Users should be able to place any pieces in editor screen
    - (g) Users should be able to rotate pieces in editor screen
    - (h) Clicking on empty or reset buttons should update the board accordingly
    - (i) User should be able to change board colours
    - (j) User should be able to change program settings (e.g. fullscreen or volume)
  6. Game UI should improve player experience
    - (a) Selected pieces should be clearly marked with a visual indicator
    - (b) Indicator showing available squares to move to when clicking on a piece
    - (c) Destroying a piece should display a visual and audio cue

- (d) Captured pieces should be displayed for each player
  - (e) Status message should display current status of the game (whose turn it is, move a piece, game won etc.)
  - (f) Move list should display played moves in string notation
  - (g) Mouse cursor icon should change depending on context
7. GUI design should be functional and display concise information
- (a) GUI should always remain responsive throughout the running of the program
  - (b) Program should be divided into separate sections with their own menus and functionality (e.g. title page, settings)
  - (c) Navigation buttons (e.g. return to menu) should concisely display their functionality
  - (d) UI should contain exit and help buttons
  - (e) UI should be designed for clarity in mind and visually pleasing
  - (f) Application window should be draggable and resizable

### 1.2.2 Other User Considerations

Although my current primary client is Mr Myslov, I aim to make my program shareable and accessible, so other parties who would like to try laser chess can access a comprehensive implementation of the game, which currently is not readily available online. Additionally, the code should be concise and well commented, complemented by proper documentation, so other parties can edit and implement additional features such as multiplayer to their own liking.

## 1.3 Research

Before proceeding with the actual implementation of the game, I will have to conduct research to plan out the fundamental architecture of the game. Reading on available information online, prior research will prevent me from committing unnecessary time to potentially inadequate ideas or code. I will consider the following areas: board representation, CPU techniques and GUI framework.

### 1.3.1 Board Representation

Board representation is the use of a data structure to represent the state of all pieces on the chessboard, and the state of the game itself, at any moment. It is the foundation on which other aspects such as move generation and the evaluation function are built upon, with different methods of implementation having their own advantages and disadvantages on simplicity, execution efficiency and memory footprint. Every board representation can be classified into two categories: piece-centric or square-centric. Piece-centric representations involve keeping track of all pieces on the board and their associated position. Conversely, square-centric representations track every available square, and if it is empty or occupied by a piece. The following are descriptions of various board representations with their respective pros and cons.

### Square list

Square list, a square-centric representation, involves the encoding of each square residing in a separately addressable memory element, usually in the form of an 8x8 two-dimensional array. Each array element would identify which piece, if any, occupies the given square. A common piece encoding could involve using the integers 1 for a pawn, 2 for knight, 3 for bishop, and + and - for white and black respectively (e.g. a white knight would be +2). This representation is easy to understand and implement, and has easy support for multiple chess variants with different board sizes. However, it is computationally inefficient as nested loop commands must be used in frequently called functions, such as finding a piece location. Move generation is also problematic, as each move must be checked to ensure that it does not wrap around the edge of the board.

### 0x88

0x88, another square-centric representation, is an 128-byte one-dimensional array, equal to the size of two adjacent chessboards. Each square is represented by an integer, with two nibbles used to represent the rank and file of the respective square. For example, the 8-integer 0x42 (0100 0010) would represent the square (4, 2) in zero-based numbering. The advantage of 0x88 is that faster bitwise operations are used for computing piece transformations. For example, add 16 to the current square number to move to the square on the row above, or add 1 to move to the next column. Moreover, 0x88 allows for efficient off-the-board detection. Every valid square number is under 0x88 in hex (0111 0111), and by performing a bitwise AND operation between the square number and 0x88 (1000 1000), the destination square can be shown to be invalid if the result is non-zero (i.e. contains 1 on 4th or 8th bit).

### Bitboards

Bitboards, a piece-centric representation, are finite sets of 64 elements, one bit per square. To represent the game, one bitboard is needed for each piece-type and colour, stored as an array of bitboards as part of a position object. For example, a player could have a bitboard for white pawns, where a positive bit indicates the presence of the pawn. Bitboards are fast to incrementally update, such as flipping bits at the source and destination positions for a moved piece. Moreover, bitmaps representing static information, such as spaces attacked by each piece type, can be pre-calculated, and retrieved with a single memory fetch at a later time. Additionally, bitboards can operate on all squares in parallel using bitwise operations, notably, a 64-bit CPU can perform all operations on a 64-bit bitboard in one cycle. Bitboards are therefore far more execution efficient than other board representations. However, bitboards are memory-intensive and may be sparse, sometimes only containing a single bit in 64. They require more source code, and are problematic for devices with a limited number of process registers or processor instruction cache.

#### 1.3.2 CPU techniques

##### Minimax

Minimax is a backtracking algorithm that evaluates the best move given a certain depth, assuming optimal play by both players. A game tree of possible moves is formulated, until the leaf node reaches a specified depth. Using a heuristic evaluation function, minimax recursively assigns each node an evaluation based on the following rules:

- If the node represents a white move, the node's evaluation is the *maximum* of the evaluation of its children
- If the node represents a black move, the node's evaluation is the *minimum* of the evaluation of its children

Thus, the algorithm *minimizes* the loss involved when the opponent chooses the move that gives *maximum* loss.

Several additional techniques can be implemented to improve upon minimax. For example, transposition tables are large hash tables storing information about previously reached positions and their evaluation. If the same position is reached via a different sequence of moves, the cached evaluation can be retrieved from the table instead of evaluating each child node, greatly reducing the search space of the game tree. Another, such as alpha-beta pruning can be stacked and applied, which eliminates the need to search large portions of the game tree, thereby significantly reducing the computational time.

### Monte-Carlo Tree Search

Monte-Carlo Tree Search (MCTS) involves playouts, where games are played to its end by selecting random moves. The result of each playout is then backpropagated up the game tree, updating the weight of nodes visited during the playout, meaning the algorithm successively improves at accurately estimating the values of the most promising moves. MCTS periodically evaluates alternatives to the currently perceived optimal move, and could thereby discover a better, otherwise overlooked, path. Another benefit is that it does not require an explicit evaluation function, as it relies on statistical sampling as opposed to developed theory on the game state. Additionally, MCTS is scalable and may be parallelized, making it suitable for distributed computing or multi-core architectures. However, the rate of tree growth is exponential, requiring huge amounts of memory. In addition, MCTS requires many iterations to be able to reliably decide the most efficient path.

#### 1.3.3 GUI framework

##### Pygame

Pygame is an open-source Python module geared for game development. It offers abundant yet simple APIs for drawing sprites and game objects on a screen-canvas, managing user input, audio et cetera. It also has good documentation, an extensive community, and receives regular updates through its community edition. Although it has greater customizability in drawing custom bitmap graphics and control over the mainloop, it lacks built-in support for UI elements such as buttons and sliders, requiring custom implementation. Moreover, it is less efficient, using 2D pixel arrays and the RAM instead of utilising the GPU for batch rendering, being single-threaded, and running on an interpreted language.

##### PyQt

PyQt is the Python binding for Qt, a cross-platform C++ GUI framework. PyQt contains an extensive set of documentation online, complemented by the documentation and forums for its C++ counterpart. Unlike Pygame, PyQt contains many widgets for common UI elements, and support for concurrency within the framework. Another advantage in using PyQt is its development ecosystem, with peripheral applications such as Qt Designer for layouts, QML for user interfaces, and QSS for styling. Although it is not open-source, containing a commercial

licensing plan, I have no plans to commercialize the program, and can therefore utilise the open-source license.

### OpenGL

Python contains multiple bindings for OpenGL, such as PyOpenGL and ModernGL. Being a widely used standard, OpenGL has the best documentation and support. It also boasts the highest efficiency, designed to be implemented using hardware acceleration through the GPU. However, its main disadvantage is the required complexity compared to the previous frameworks, being primarily a graphical API and not for developing full programs.

## 1.4 Proposed Solution

### 1.4.1 Language

The two main options regarding programming language choice, and their pros and cons, are as listed:

		Python	
		Pros	Cons
		<ul style="list-style-type: none"><li>• Versatile and intuitive, uses simple syntax and dynamic typing</li><li>• Supports both object-oriented and procedural programming</li><li>• Rich ecosystem of third-party modules and libraries</li><li>• Interpreted language, good for portability and easy debugging</li></ul>	<ul style="list-style-type: none"><li>• Slow at runtime</li><li>• High memory consumption</li></ul>
		Javascript	
		Pros	Cons

- Generally faster runtime than Python
  - Simple, dynamically typed and automatic memory management
  - Versatile, easy integration with both server-side and front-end
  - Extensive third-party modules
  - Also supports object-oriented programming
  - Mainly focused for web development
  - Comprehensive knowledge of external frameworks (i.e. Electron) needed for developing desktop applications
- 

I have chosen Python as the programming language for this project. This is mainly due to its extensive third-party modules and libraries available. Python also provides many different GUI frameworks for desktop applications, whereas options are limited for JavaScript due to its focus on web applications. Moreover, the amount of resources and documentation online will prove invaluable for the development process.

Although Python generally has worse performance than JavaScript, speed and memory efficiency are not primary objectives in my project, and should not affect the final program. Therefore, I have prioritised Python's simpler syntax over JavaScript's speed. Being familiar with Python will also allow me to divert more time for development instead of researching new concepts or fixing unfamiliar bugs.

#### 1.4.2 Development Environment

A good development environment improves developer experiences, with features such as auto-indentation and auto-bracket completion for quicker coding. The main development environments under consideration are: Visual Studio Code (VS Code), PyCharm and Sublime Text. I have decided to use VS Code due to its greater library of extensions over Sublime, and its more user-friendly implementation of features such as version control and GitHub integration. Moreover, VS Code contains many handy features that will speed up the development process, such as its built-in debugging features. Although PyCharm is an extensive IDE, its default features can be supplemented by VS Code extensions. Additionally, VS Code is more lightweight and customizable, and contains vast documentation online.

#### 1.4.3 Source Control

A Source Control Tool automates the process of tracking and managing changes in source code. A good source control tool will be essential for my project. It provides the benefits of: protecting the code from human errors (i.e. accidental deletion), enabling easy code experimentation on a clone created through branching from the main project, and by tracking changes through the code history, enabling easier debugging and rollbacks. For my project, I have chosen Git as my version control tool, as it is open-source and provides a more user-friendly interface and documentation over alternatives such as Azure DevOps, and contains sufficient functionality for a small project like mines.

#### 1.4.4 Techniques

I have decided on employing the following techniques, based on the pros and cons outlined in the research section above.

##### Board representation

I have chosen to use a bitboard representation for my game. The main consideration was computational efficiency, as a smooth playing experience should be ensured regardless of device used. Bitboards allow for parallel bitwise operations, especially as most modern devices nowadays run on 64-bit architecture CPUs. With bitboards being the mainstream implementation, documentation should also be plentiful.

##### CPU techniques

I have chosen minimax as my searching algorithm. This is due to its relatively simplistic implementation and evaluation accuracy. Additionally, Monte-Carlo Tree Search is computationally intensive, with a high memory requirement and time needed to run with a sufficient number of simulations, which I do not have.

##### GUI framework

I have chosen Pygame as my main GUI framework. This is due to its increased flexibility, in creating custom art and widgets compared to PyQt's defined toolset, which is tailored towards building commercial office applications. Although Pygame contains more overhead and boilerplate code to create standard functionality, I believe that the increased control is worth it for a custom game such as laser chess, which requires dynamic rendering of elements such as the laser beam.

I will also integrate Pygame together with ModernGL, using the convenient APIs in for handling user input and sprite drawing, together with the speed of OpenGL to draw shaders and any other effect overlays.

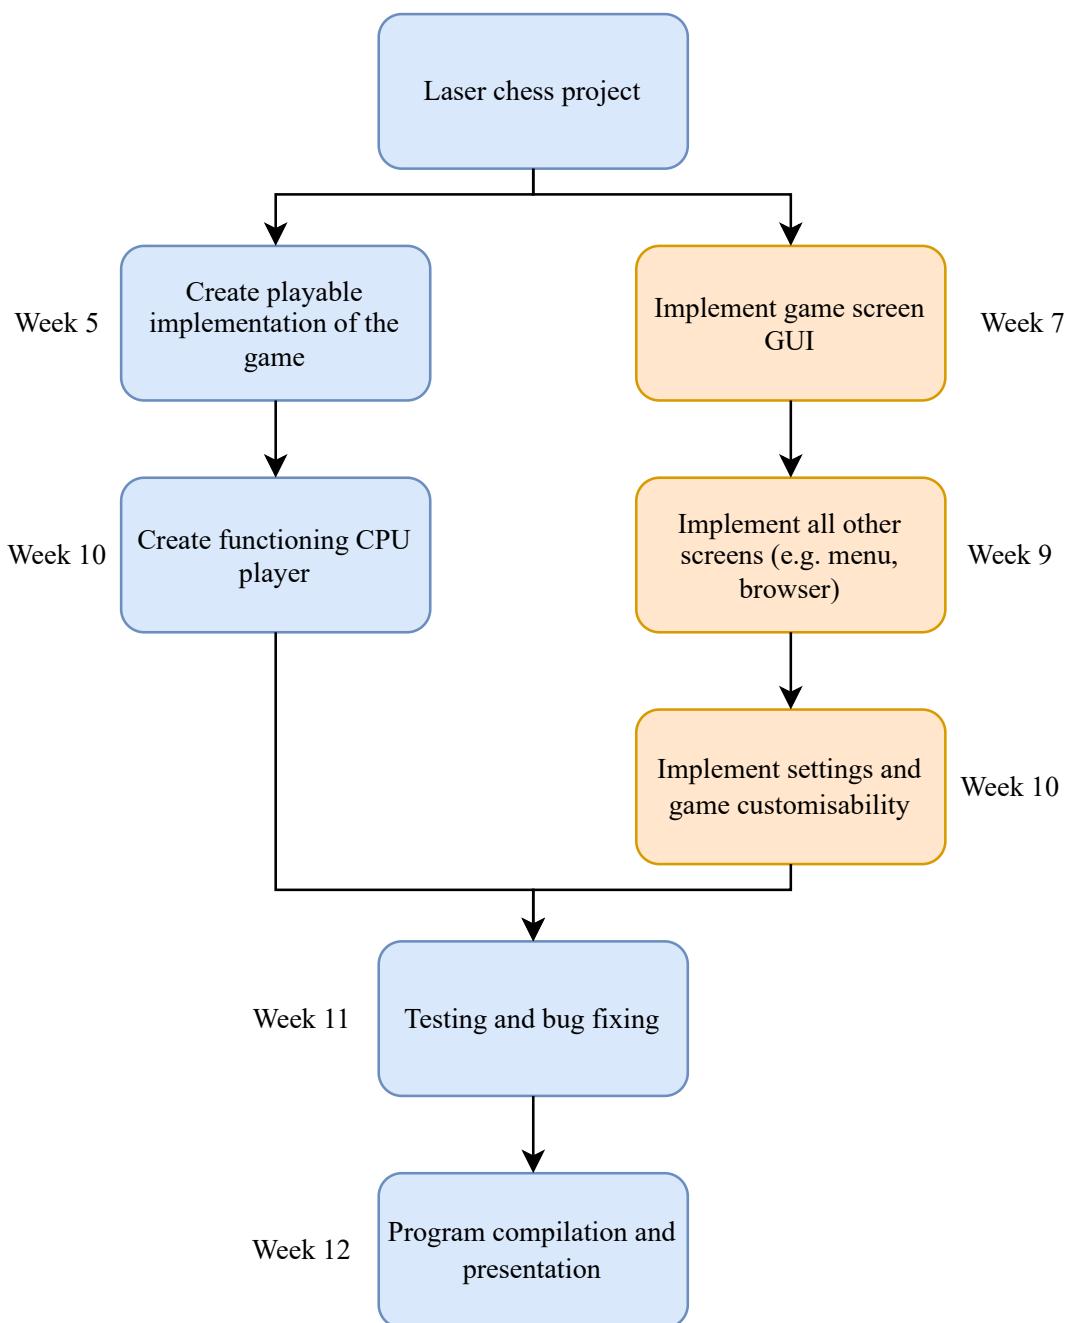

### 1.5 Limitations

I have agreed with my client that due to the multiple versions of Laser Chess that exist online, together with a lack of regulation, an implementation that adheres to the general rules of Laser Chess, and not strictly to a specific version, is acceptable.

Moreover, due to the time constraints on both my schedules for exams and for the date of the tournament, the game only has to be presented in a functional state, and not polished for release, with extra work such as porting to a wide range of OS systems.

### 1.6 Critical Path Design

In order to meet my client's requirement of releasing the game before the next field day, I have given myself a time limit of 12 weeks to develop my game, and have created the following critical path diagram to help me adhere to completing every milestone within the time limit.

# Chapter 2

## Design

### 2.1 System Architecture

In this section, I will lay out the overall logic, and an overview of the steps involved in running my program. By decomposing the program into individual abstracted stages, I can focus on the workings and functionality of each section individually, which makes documenting and coding each section easier. I have also included a flowchart to illustrate the logic of each screen of the program.

I will also create an abstracted GUI prototype in order to showcase the general functionality of the user experience, while acting as a reference for further stages of graphical development. It will consist of individually drawn screens for each stage of the program, as shown in the top-level overview. The elements and layout of each screen are also documented below.

The following is a top-level overview of the logic of the program:

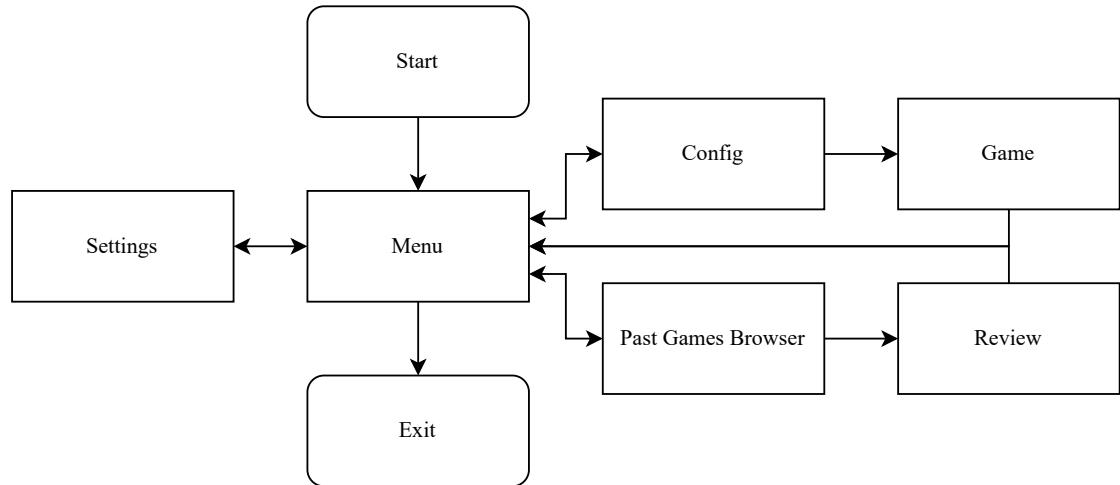

Figure 2.1: Flowchart for Program Overview

### 2.1.1 Main Menu

Figure 2.2: Main Menu screen prototype

The main menu will be the first screen to be displayed, providing access to different stages of the game. The GUI should be simple yet effective, containing clearly-labelled buttons for the user to navigate to different parts of the game.

### 2.1.2 Settings

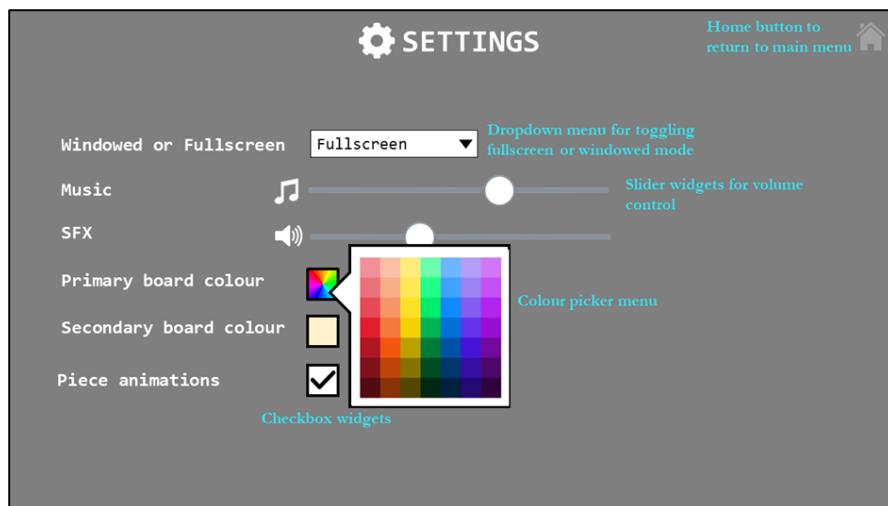

Figure 2.3: Settings screen prototype

The settings menu allows for the user to customise settings related to the program as a whole. The settings will be changed via GUI elements such as buttons and sliders, offering the ability

to customize display mode, volume, board colour etc. Changes to settings will be stored in an intermediate code class, then stored externally into a JSON file. Game settings will instead be changed in the Config screen.

The setting screen should provide a user-friendly interface for changing the program settings intuitively; I have therefore selected appropriate GUI widgets for each setting:

- Windowed or Fullscreen - Drop-down list for selecting between pre-defined options
- Music and SFX - Slider for selecting audio volume, a continuous value
- Board colour - Colour grid for the provision of multiple pre-selected colours
- Piece animation - Checkbox for toggling between on or off

Additionally, each screen is provided with a home button icon on the top right (except the main menu), as a shortcut to return to the main menu.

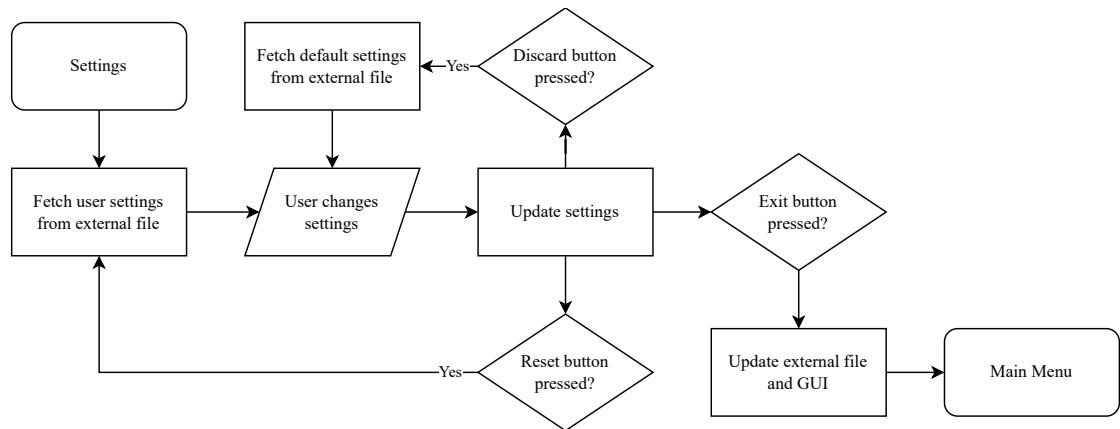

Figure 2.4: Flowchart for Settings

### 2.1.3 Past Games Browser

Figure 2.5: Browser screen prototype

The Past Games Browser menu displays a list of previously played games to be replayed. When selecting a game, the replay will render out the saved FEN string into a board position identical to the one played previously, except the user is limited to replaying back and forth between recorded moves. The menu also offers the functionality of sorting games in terms of time, game length etc.

For the GUI, previous games will be displayed on a strip, scrolled through by a horizontal slider. Information about the game will be displayed for each instance, along with the option to copy the FEN string to be stored locally or to be entered into the Review screen. When choosing a past game, a green border will appear to show the current selection, and double clicking enters the user into the full replay mode. While replaying the game, the GUI will appear identical to an actual game. However, the user will be limited to scrolling throughout the moves via the left and right arrow keys.

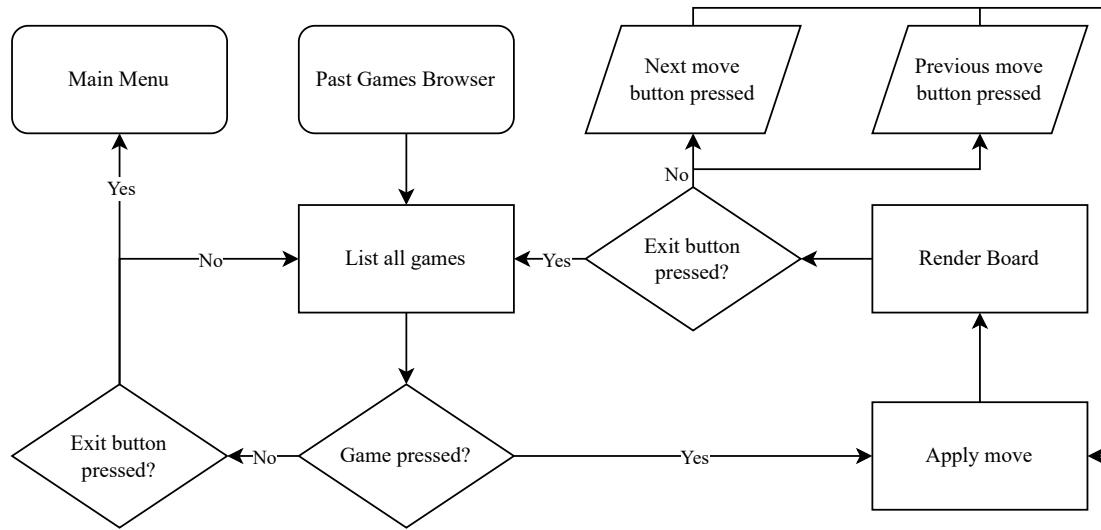

Figure 2.6: Flowchart for Browser

#### 2.1.4 Config

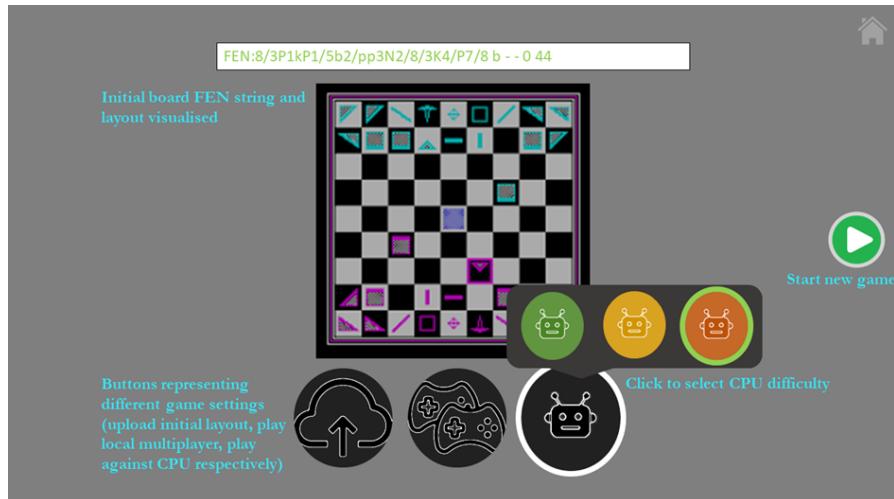

Figure 2.7: Config screen prototype

The config screen comes prior to the actual gameplay screen. Here, the player will be able to change game settings such as toggling the CPU player, time duration, playing as white or black etc.

The config menu is loaded with the default starting position. However, players may enter their own FEN string as an initial position, with the central board updating responsively to give a visual representation of the layout. Players are presented with the additional options to play against a friend, or against a CPU, which displays a drop-down list when pressed to select the CPU difficulty.

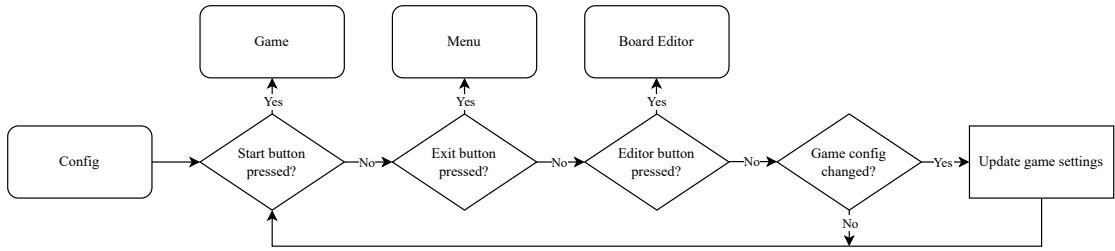

Figure 2.8: Flowchart for Config

### 2.1.5 Game

Figure 2.9: Game screen prototype

During the game, handling of the game logic, such as calculating player turn, calculating CPU moves or laser trajectory, will be computed by the program internally, rendering the updated GUI accordingly in a responsive manner to provide a seamless user experience.

In the game screen, the board is positioned centrally on the screen, surrounded by accompanying widgets displaying information on the current state of the game. The main elements include:

- Status text - displays information on the game state and prompts for each player move
- Rotation buttons - allows each player to rotate the selected piece by 90° for their move
- Timer - displays available time left for each player
- Draw and forfeit buttons - for the named functionalities, confirmed by pressing twice
- Piece display - displays material captured from the opponent for each player

Additionally, the current selected piece will be highlighted, and the available squares to move to will also contain a circular visual cue. Pieces will either be moved by clicking the

target square, or via a drag-and-drop mechanism, accompanied by responsive audio cues. These implementations aim to improve user-friendliness and intuitiveness of the program.

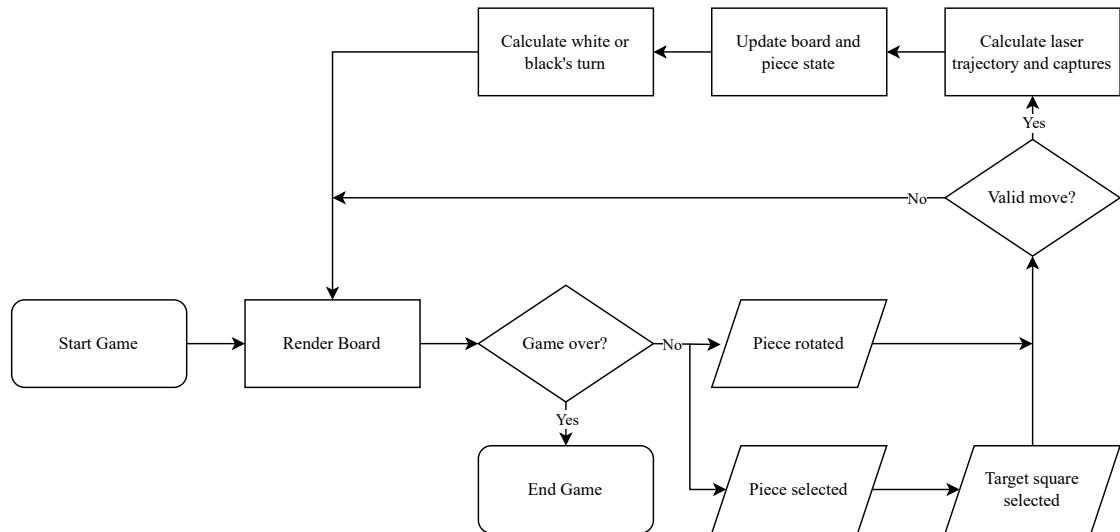

Figure 2.10: Flowchart for Game

### 2.1.6 Board Editor

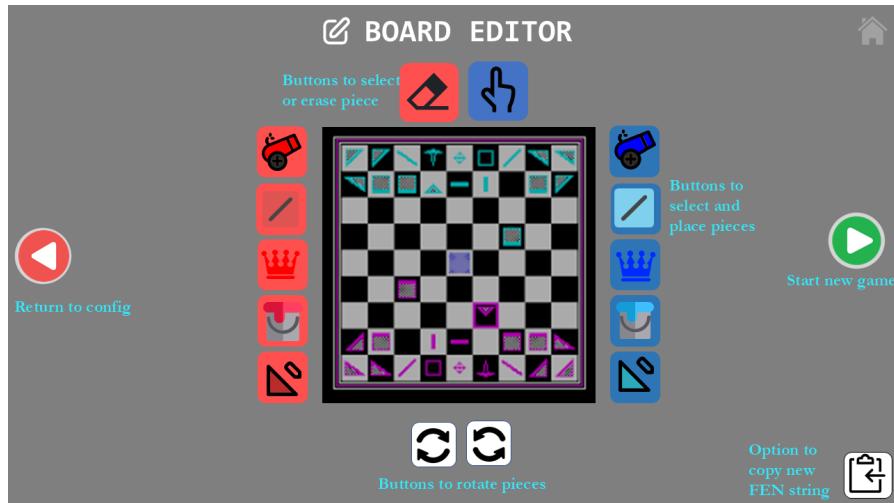

Figure 2.11: Editor screen prototype

The editor screen is used to configure the starting position of the board. Controls should include the ability to place all piece types of either colour, to erase pieces, and easy board manipulation shortcuts such as dragging pieces or emptying the board.

For the GUI, the buttons should clearly represent their functionality, through the use of icons and appropriate colouring (e.g. red for delete).

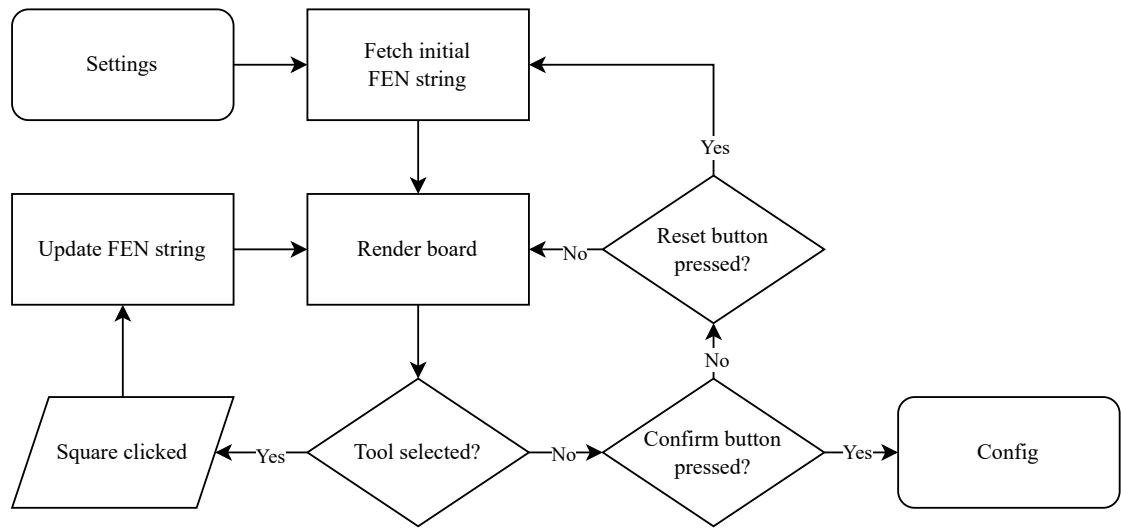

Figure 2.12: Flowchart for board editor

## 2.2 Algorithms and Techniques

### 2.2.1 Minimax

Minimax is a backtracking algorithm commonly used in zero-sum games used to determine the score according to an evaluation function, after a certain number of perfect moves. Minimax aims to minimize the maximum advantage possible for the opponent, thereby minimizing a player's possible loss in a worst-case scenario. It is implemented using a recursive depth-first search, alternating between minimizing and maximizing the player's advantage in each recursive call.

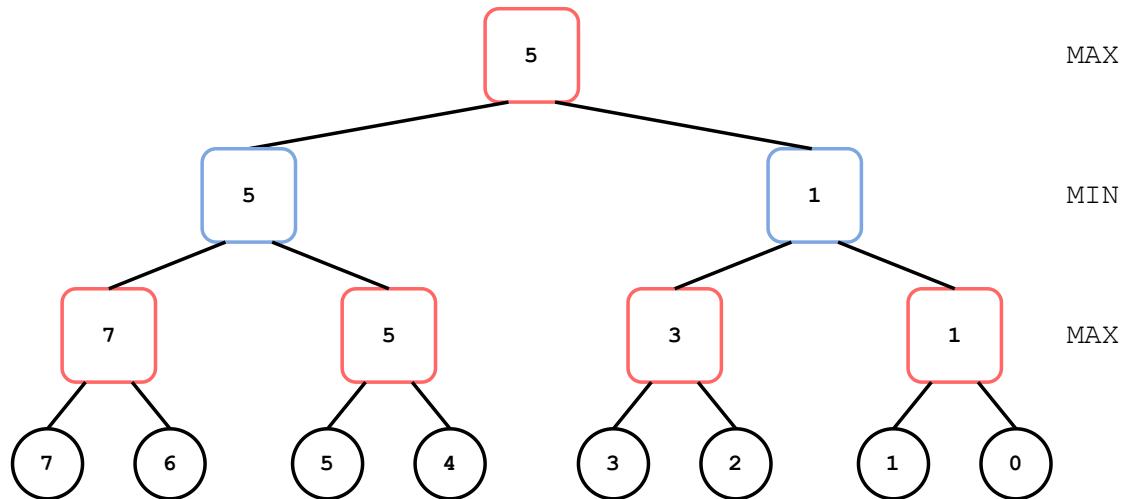

Figure 2.13: Example minimax tree

For the example minimax tree show in Figure 2.13, starting from the bottom leaf node

evaluations, the maximising player would choose the highest values (7, 5, 3, 1). From those values, the minimizing player would choose the lowest values (5, 1). The final value chosen by the maximum player would therefore be the highest of the two, 5.

Implementation in the form of pseudocode is shown below:

---

**Algorithm 1** Minimax pseudocode
 

---

```

function MINIMAX(node, depth, maximisingPlayer)
  if depth = 0 OR node equals game over then
    return EVALUATE
  end if

  if maximisingPlayer then
    value ← −∞
    for child of node do
      value ← MAX(value, MINIMAX(child, depth − 1, false))
    end for
    return value
  else
    value ← +∞
    for child of node do
      value ← MIN(value, MINIMAX(child, depth − 1, true))
    end for
    return value
  end if
end function
```

---

## 2.2.2 Minimax improvements

### Alpha-beta pruning

Alpha-beta pruning is a search algorithm that aims to decrease the number of nodes evaluated by the minimax algorithm. Alpha-beta pruning stops evaluating a move in the game tree when one refutation is found in its child nodes, proving the node to be worse than previously-examined alternatives. It does this without any potential of pruning away a better move. The algorithm maintains two values: alpha and beta. Alpha ( $\alpha$ ), the upper bound, is the highest value that the maximising player is guaranteed of; Beta ( $\beta$ ), the lower bound, is the lowest value that the minimizing player is guaranteed of. If the condition  $\alpha \geq \beta$  for a node being evaluated, the evaluation process halts and its remaining children nodes are ‘pruned’.

This is shown in the following maximising example:

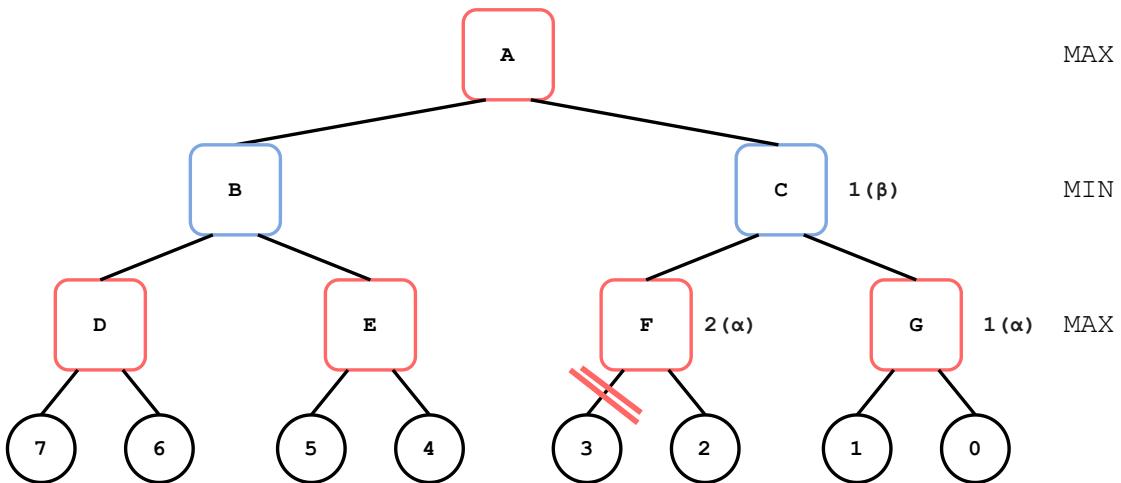

Figure 2.14: Example minimax tree with alpha-beta pruning

Since minimax is a depth-first search algorithm, nodes  $C$  and  $G$  and their  $\alpha$  and  $\beta$  have already been searched. Next, at node  $F$ , the current  $\alpha$  and  $\beta$  are  $-\infty$  and 1 respectively, since the  $\beta$  is passed down from node  $C$ . Searching the first leaf node, the  $\alpha$  subsequently becomes  $\alpha = \max(-\infty, 2)$ . This means that the maximising player at this depth is already guaranteed an evaluation of 2 or greater. Since we know that the minimising player at the depth above is guaranteed a value of 1, there is no point in continuing to search node  $F$ , a node that returns a value of 2 or greater. Hence at node  $F$ , where  $\alpha \geq \beta$ , the branches are pruned.

Alpha-beta pruning therefore prunes insignificant nodes by maintain an upper bound  $\alpha$  and lower bound  $\beta$ . This is an essential optimization as a simple minimax tree increases exponentially in size with each depth ( $O(b^d)$ , with branching factor  $b$  and  $d$  ply depth), and alpha-beta reduces this and the associated computational time considerably.

The pseudocode implementation is shown below:

---

**Algorithm 2** Minimax with alpha-beta pruning pseudocode

---

```

function MINIMAX(node, depth,  $\alpha$ ,  $\beta$ , maximisingPlayer)
    if depth = 0 OR node equals game over then
        return EVALUATE
    end if

    if maximisingPlayer then
        value  $\leftarrow -\infty$ 
        for child of node do
            value  $\leftarrow \text{MAX}(\text{value}, \text{MINIMAX}(\text{child}, \text{depth} - 1, \alpha, \beta, \text{false}))$ 
            if value >  $\beta$  then break
            end if
             $\alpha \leftarrow \text{MAX}(\alpha, \text{value})$ 
        end for
        return value
    else
        value  $\leftarrow +\infty$ 
        for child of node do
            value  $\leftarrow \text{MIN}(\text{value}, \text{MINIMAX}(\text{child}, \text{depth} - 1, \alpha, \beta, \text{true}))$ 
            if value <  $\alpha$  then break
            end if
             $\beta \leftarrow \text{MIN}(\beta, \text{value})$ 
        end for
        return value
    end if
end function

```

---

**Transposition Tables & Zobrist Hashing**

Transition tables, a memoisation technique, again greatly reduces the number of moves searched. During a brute-force minimax search with a depth greater than 1, the same positions may be searched multiple times, as the same position can be reached from different sequences of moves. A transposition table caches these same positions (transpositions), along with its associated evaluations, meaning commonly reached positions are not unnecessarily re-searched.

Flags and depth are also stored alongside the evaluation. Depth is required as if the current search comes across a cached position with an evaluation calculated at a lower depth than the current search, the evaluation may be inaccurate. Flags are required for dealing with the uncertainty involved with alpha-beta pruning, and can be any of the following three.

**Exact** flag is used when a node is fully searched without pruning, and the stored and fetched evaluation is accurate.

**Lower** flag is stored when a node receives an evaluation greater than the  $\beta$ , and is subsequently pruned, meaning that the true evaluation could be higher than the value stored. We are thus storing the  $\alpha$  and not an exact value. Thus, when we fetch the cached value, we have to recheck if this value is greater than  $\beta$ . If so, we return the value and this branch is pruned (fail high); If not, nothing is returned, and the exact evaluation is calculated.

**Upper** flag is stored when a node receives an evaluation smaller than the  $\alpha$ , and is subsequently pruned, meaning that the true evaluation could be lower than the value stored. Similarly, when we fetch the cached value, we have to recheck if this value is lower than  $\alpha$ . Again, the current branch is pruned if so (fail low), and an exact evaluation is calculated if not.

The pseudocode implementation for transposition tables is shown below:

---

**Algorithm 3** Minimax with transposition table pseudocode

---

```

function MINIMAX(node, depth,  $\alpha$ ,  $\beta$ , maximisingPlayer)
    hash_key  $\leftarrow$  HASH(node)
    entry  $\leftarrow$  GETENTRY(hash_key)

    if entry.hash_key = hash_key AND entry.hash_key  $\geq$  depth then
        if entry.hash_key = EXACT then
            return entry.value
        else if entry.hash_key = LOWER then
             $\alpha \leftarrow \text{MAX}(\alpha, \text{entry.value})$ 
        else if entry.hash_key = UPPER then
             $\beta \leftarrow \text{MIN}(\beta, \text{entry.value})$ 
        end if
        if  $\alpha \geq \beta$  then
            return entry.value
        end if
    end if

    ...normal minimax...

    entry.value  $\leftarrow$  value
    entry.depth  $\leftarrow$  depth
    if value  $\leq \alpha$  then
        entry.flag  $\leftarrow$  UPPER
    else if value  $\geq \beta$  then
        entry.flag  $\leftarrow$  LOWER
    else
        entry.flag  $\leftarrow$  EXACT
    end if

    return value
end function

```

---

The current board position will be used as the index for a transposition table entry. To convert our board state and bitboards into a valid index, Zobrist hashing may be used. For every square on the chessboard, a random integer is assigned to every piece type (12 in our case, 6 piece type, times 2 for both colours). To initialise a hash, the random integer associated with the piece on a specific square undergoes a XOR operation with the existing hash. The hash is incrementally update with XOR operations every move, instead of being recalculated from scratch improving computational efficiency. Using XOR operations also allows moves to be reversed, proving useful for the functionality to scroll through previous moves. A Zobrist hash is also a better candidate than FEN strings in checking for threefold-repetition, as they are less

intensive to calculate for every move.

The pseudocode implementation for Zobrist hashing is shown below:

---

**Algorithm 4** Zobrist hashing pseudocode

---

*RANDOMINTS represents a pre-initialised array of random integers for each piece type for each square*

```

function HASH _ BOARD(board)
    hash ← 0
    for each square on board do
        if square is not empty then
            hash ⊕ RANDOMINTS[square][piece on square]
        end if
    end for
    return hash
end function

function UPDATEHASH(hash, move)
    hash ⊕ RANDOMINTS[source square][piece]
    hash ⊕ RANDOMINTS[destination square][piece]
    if red to move then
        hash ⊕ hash for red to move ▷ Hash needed for move colour, as two identical positions
        are different if the colour to move is different
    end if
    return hash
end function

```

---

### Iterative Deepening

Iterative deepening builds upon the previous alpha-beta and caching improvements. A search is initiated at a depth of one ply, which upon finishing, another starts at depth two, three, and increases until the max depth is reached or time allocated is up. Although this means that more nodes are searched, the improvements come from the fact that the best move (PV-Move) found by a lower depth search, can be used as the first move searched on the next higher depth search. This increases the chance of pruning, reducing the net number of nodes searched, and also provides a 'fallback' move if a higher depth search is interrupted.

#### 2.2.3 Board Representation

##### FEN string

Forsyth-Edwards Notation (FEN) notation provides all information on a particular position in a chess game. I intend to implement methods parsing and generating FEN strings in my program, in order to load desired starting positions and save games for later play. Deviating from the classic 6-part format, a custom FEN string format will be required for our laser chess game, accommodating its different rules from normal chess.

Our custom format implementation is show by the example below:

sc3ncfancpb2/2pc7/3Pd7/pa1Pc1rbra1pb1Pd/pb1Pd1RaRb1pa1Pc/6pb3/7Pa2/2PdNaFaNa3Sa

r

Our FEN string format contains two parts, denoted by the space between them:

- Part 1: Describes the location of each piece. The construction of this part is defined by the following rules:
  - The board is read from top-left to bottom-right, row by row
  - A number represents the number of empty squares before the next piece
  - A capital letter represents a blue piece, and a lowercase letter represents a red piece
  - The letters *F*, *R*, *P*, *N*, *S* stand for the pieces Pharaoh, Scarab, Pyramid, Anubis and Sphinx respectively
  - Each piece letter is followed by the lowercase letters *a*, *b*, *c* or *d*, representing a 0°, 90°, 180° and 270° degree rotation respectively
- Part 2: States the active colour, *b* means blue to move, *r* means red to move

Having inputted the desired FEN string board configuration in the config menu, the bitboards for each piece will be initialised with the following functions:

---

**Algorithm 5** FEN string pseudocode
 

---

```

function PARSE_FEN_STRING(fen_string, board)
  part_1, part_2 ← SPLIT(fen_string)
  rank ← 8
  file ← 0

  for character in part_1 do
    square ← rank × 8 + file
    if character is alphabetic then
      if character is lower then
        board.bitboards[red][character] | 1 << character
      else
        board.bitboards[blue][character] | 1 << character
      end if
    else if character is numeric then
      file ← file + character
    else if character is / then
      rank ← rank - 1
      file ← file + 1
    else
      file ← file + 1
    end if

    if part_2 is b then
      board.active_colour ← b
    else
      board.active_colour ← r
    end if
  end for
end function
  
```

---

The function first processes every piece and corresponding square in the FEN string, modifying each piece bitboard using a bitwise OR operator, with a 1 shifted over to the correctly occupied square using a Left-Shift operator. For the second part, the active colour property of the board class is initialised to the correct player.

### Bitboards

Bitboards are an array of bits representing a position or state of a board game. Multiple bitboards are used with each representing a different property of the game (e.g. scarab position and scarab rotation), and can be masked together or transformed to answer queries about positions. Bitboards offer an efficient board representation, its performance primarily arising from the speed of parallel bitwise operations used to transform bitboards. To map each board square to a bit in each number, we will assign each square from left to right, with the least significant bit (LSB) assigned to the bottom-left square (A1), and the most significant bit (MSB) to the top-right square (J8).

<b>8</b>	70	71	72	73	74	75	76	77	78	79
<b>7</b>	60	61	62	63	64	65	66	67	68	69
<b>6</b>	50	51	52	53	54	55	56	57	58	59
<b>5</b>	40	41	42	43	44	45	46	47	48	49
<b>4</b>	30	31	32	33	34	35	36	37	38	39
<b>3</b>	20	21	22	23	24	25	26	27	28	29
<b>2</b>	10	11	12	13	14	15	16	17	18	19
<b>1</b>	0	1	2	3	4	5	6	7	8	9
	<b>a</b>	<b>b</b>	<b>c</b>	<b>d</b>	<b>e</b>	<b>f</b>	<b>g</b>	<b>h</b>	<b>j</b>	<b>k</b>

Figure 2.15: Square to bit position mapping

Firstly, we need to initialise each bitboard and place 1s in the correct squares occupied by pieces. This is achieved whilst parsing the FEN-string, as shown in Algorithm 5. Secondly, we should implement an approach to calculate possible moves using our computed bitboards. We can begin by producing a bitboard containing the locations of all pieces, achieved through combining every piece bitboard with bitwise OR operations:

```
all_pieces_bitboard = white_pharaoh_bitboard | black_pharaoh_bitboard |
                     white_scarab_bitboard ...
```

Now, we can utilize this aggregated bitboard to calculate possible positional moves for each piece. For each piece, we can shift the entire bitboard to an adjacent target square (since every piece can only move one adjacent square per turn), and perform a bitwise AND operator with the bitboard containing all pieces, to determine if the target square is already occupied by an existing piece. For example, if we want to compute if the square to the left of our selected piece

is available to move to, we will first shift every bit right (as the lowest square index is the LSB on the right, see diagram above), as demonstrated in the following 5x5 example:

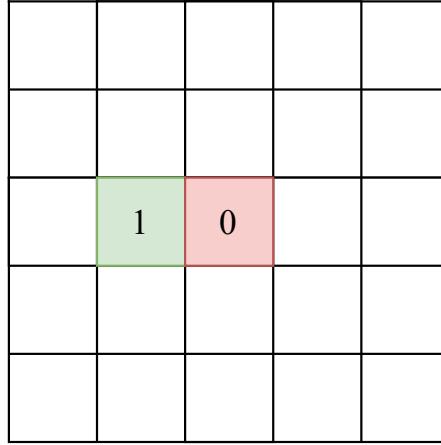

Figure 2.16: `shifted_bitboard = piece_bitboard >> 1`

Where green represents the target square shifted into, and orange where the piece used to be. We can then perform a bitwise AND operation with the complement of the all pieces bitboard, where a square with a result of 1 represents an available target square to move to.

```
available_squares_right = (piece_bitboard >> 1) & ~all_pieces_bitboard
```

However, if the piece is on the leftmost A file, and is shifted to the right, it will be teleported onto the J file on the rank below, which is not a valid move. To prevent these erroneous moves for pieces on the edge of the board, we can utilise an A file mask to mask away any valid moves, as demonstrated below:

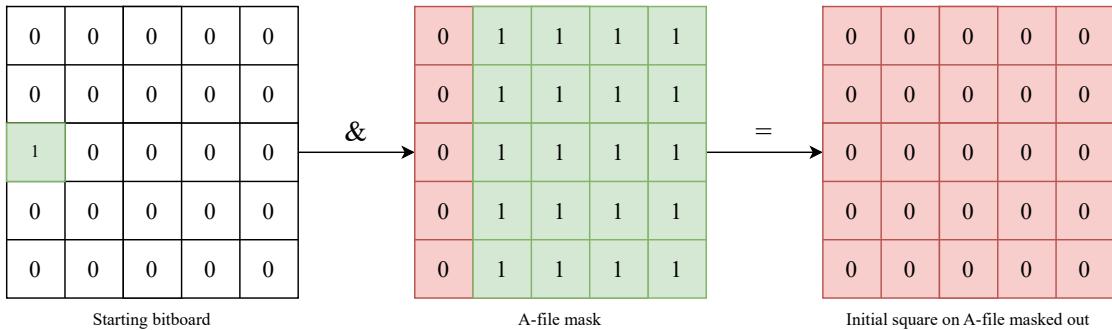

Figure 2.17: A-file mask example

This approach uses the logic that a piece on the A file can never move to a square on the left. Therefore, when calculating if a piece can move to a square on the left, we apply a bitwise AND operator with a mask where every square on the A file is 0; If a piece was on the A file, it will become 0, leaving no possible target squares to move to. The same approach can be mirrored for the far-right J file.

In theory, we do not need to implement the same solution for clipping in regards to ranks, as they are removed automatically by overflow or underflow when shifting bits too far. Our final function to calculate valid moves combines all the logic above: Shifting the selected piece in all 9 adjacent directions by their corresponding bits, masking away pieces trying to move into the edge of the board, combining them with a bitwise OR operator, and finally masking it with the all pieces bitboard to detect which squares are not currently occupied:

---

**Algorithm 6** Finding valid moves pseudocode

---

```

function FIND_VALID_MOVES(selected_square)
    masked_a_square ← selected_square & A_FILE_MASK
    masked_j_square ← selected_square & J_FILE_MASK

    top_left ← masked_a_square << 9
    top_left ← masked_a_square << 9
    top_middle ← selected_square << 10
    top_right ← masked_ << 11
    middle_right ← masked_ << 1
    bottom_right ← masked_ >> 9
    bottom_middle ← selected_square >> 10
    bottom_left ← masked_a_square >> 11
    middle_left ← masked_a_square >> 1

    possible_moves = top_left | top_middle | top_right | middle_right | bottom_right |
    bottom_middle | bottom_left | middle_left
    valid_moves = possible_moves & ~ ALL_PIECES_BITBOARD

    return valid_moves
end function

```

---

#### 2.2.4 Evaluation Function

The evaluation function is a heuristic algorithm to determine the relative value of a position. It outputs a real number corresponding to the advantage given to a player if reaching the analysed position, usually at a leaf node in the minimax tree. The evaluation function therefore provides the values on which minimax works on to compute an optimal move.

In the majority of evaluation functions, the most significant factor determining the evaluation is the material balance, or summation of values of the pieces. The hand-crafted evaluation function is then optimised by tuning various other positional weighted terms, such as board control and king safety.

##### Material Value

Since laser chess is not widely documented, I have assigned relative strength values to each piece according to my experience playing the game:

- Pharaoh -  $\infty$
- Scarab - 200
- Anubis - 110

- Pyramid - 100

To find the number of pieces, we can iterate through the piece bitboard with the following popcount function:

---

**Algorithm 7** Popcount pseudocode

---

```
function POPCOUNT(bitboard)
    count ← 0
    while bitboard do
        count ← count + 1
        bitboard ← bitboard&(bitboard − 1)
    end while
    return count
end function
```

---

Algorithm 7 continually resets the left-most 1 bit, incrementing a counter for each loop. Once the number of pieces has been established, we multiply this number by the piece value. Repeating this for every piece type, we can thus obtain a value for the total piece value on the board.

### Piece-Square Tables

A piece in normal chess can differ in strength based on what square it is occupying. For example, a knight near the center of the board, controlling many squares, is stronger than a knight on the rim. Similarly, we can implement positional value for Laser Chess through Piece-Square Tables. PSQTs are one-dimensional arrays, with each item representing a value for a piece type on that specific square, encoding both material value and positional simultaneously. Each array will consist of 80 base values representing the piece's material value, with a bonus or penalty added on top for the location of the piece on each square. For example, the following PSQT is for the pharaoh piece type on an example 5x5 board:

0	0	0	0	0
0	0	1	0	0
0	0	0	0	0
0	0	0	0	0
0	0	0	0	0

Piece index

-10	-10	-10	-10	-10
-10	-10	-10	-10	-10
-5	-5	-5	-5	-5
0	0	0	0	0
5	5	5	5	5

Used to reference positional value in PSQT

Figure 2.18: PSQT showing the bonus position value gained for the square occupied by a pharaoh

For asymmetrical PSQTs, we would ideally like to label the board identically from both player's point of views. Although the PSQTs are displayed from the blue player's perspective (blue pharaoh at the bottom of the board), it uses indexes from the red player's perspective, as

arrays and lists are defined with index 0 being at the topleft of the board. We would like to flip the PSQTs to be reused with blue indexes, so that a generic algorithm can be used to sum up and calculate the total positional values for both players.

To utilise a PSQT for blue pieces, a special ‘FLIP’ table can be implemented:

<b>8</b>	70	71	72	73	74	75	76	77	78	79
<b>7</b>	60	61	62	63	64	65	66	67	68	69
<b>6</b>	50	51	52	53	54	55	56	57	58	59
<b>5</b>	40	41	42	43	44	45	46	47	48	49
<b>4</b>	30	31	32	33	34	35	36	37	38	39
<b>3</b>	20	21	22	23	24	25	26	27	28	29
<b>2</b>	10	11	12	13	14	15	16	17	18	19
<b>1</b>	0	1	2	3	4	5	6	7	8	9

**a    b    c    d    e    f    g    h    j    k**

Figure 2.19: FLIP table used to map a blue piece index to the red player’s perspective

The FLIP table is just an array of indexes, mapping every blue player’s index onto the corresponding red index. The following expression utilises the FLIP table to retrieve a blue player’s value from the red player’s PSQT:

```
blue_psqt_value = PHAROAH_PSQT[FLIP[square]]
```

The following function retrieves an array of bitboards representing piece positions from the board class, then sums up all the values of these pieces for both players, referencing the corresponding PSQT:

**Algorithm 8** Calculating positional value pseudocode

---

```

function CALCULATE_POSITIONAL_VALUE(bitboards, colour)
    positional_score  $\leftarrow$  0
    for all pieces do
        for square in bitboards[piece] do
            if square = 1 then
                if colour is blue then
                    positional_score  $\leftarrow$  positional_score + PSQT[piece][square]
                else
                    positional_score  $\leftarrow$  positional_score + PSQT[piece][FLIP[square]]
                end if
            end if
        end for
    end for
    return positional_score
end function

```

---

**Using valid squares**

Using Algorithm 6 for finding valid moves, we can implement two more improvements for our evaluation function: Mobility and King Safety.

**Mobility** is the number of legal moves a player has for a given position. This is advantageous in most cases, with a positive correlation between mobility and the strength of a position. To implement this, we simply loop over all pieces of the active colour, and sum up the number of valid moves obtained from the previous algorithm.

**King safety** (Pharaoh safety) describes the level of protection of the pharaoh, being the piece that determines a win or loss. In normal chess, this would be achieved usually by castling, or protection via position or with other pieces. Similarly, since the only way to lose in Laser Chess is via a laser, having pieces surrounding the pharaoh, either to reflect the laser or to be sacrificed, is a sensible tactic and improves king safety. Thus, a value for king safety can be achieved by finding the number of valid moves a pharaoh can make, and subtracting them from the maximum possible of moves (8) to find the number of surrounding pieces.

### 2.2.5 Shadow Mapping

Following the client's requirement for engaging visuals, I have decided to implement shadow mapping for my program, especially as lasers are the main focus of the game. Shadow mapping is a technique used to create graphical hard shadows, with the use of a depth buffer map. I have chosen to implement shadow mapping, instead of alternative lighting techniques such as ray casting and ray marching, as its efficiency is more suitable for real-time usage, and results are visually decent enough for my purposes.

For typical 3D shadow mapping, the standard approach is as follows:

1. Render the scene from the light's point of view
2. Extract a depth buffer texture from the render
3. Compare the distance of a pixel from the light to the value stored in the depth texture

4. If greater, there must be an obstacle in the way reducing the depth map value, therefore that pixel must be in shadow

To implement shadow casting for my 2D game, I have modified some steps and arrived on the final following workflow:

1. Render the scene with only occluding objects shown
2. Crop texture to align the center to the light position
3. To create a 1D depth map, transform Cartesian to polar coordinates, and increase the distance from the origin until a collision with an occluding object
4. Using polar coordinates for the real texture, compare the z-depth to the corresponding value from the depth map
5. Additively blend the light colour if z-depth is less than the depth map value

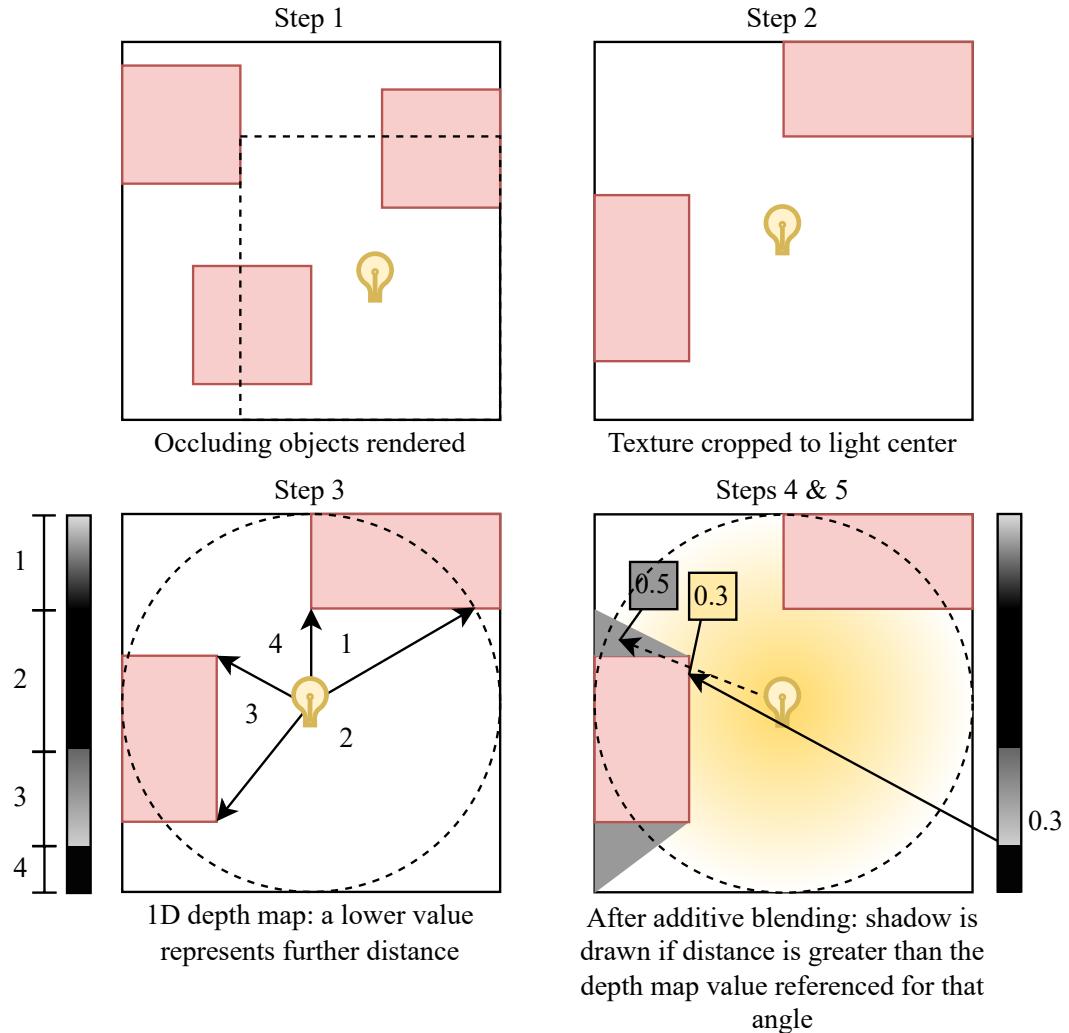

Figure 2.20: Workflow for 2D shadow mapping

Our method requires a coordinate transformation from Cartesian to polar, and vice versa. Polar to Cartesian transformation can be achieved with trigonometry, forming a right-angled triangle in the center and using the following two equations:

$$x = r \cos(\theta)$$

$$y = r \sin(\theta)$$

Cartesian to polar can also similarly be achieved with the right-angled triangle, finding the radius with the Pythagorean theorem, and the angle with arctan. However, since the range of the arctan function is only a half-circle ( $\frac{\pi}{2} < \theta < \frac{3\pi}{2}$ ), we will have to use the atan2 function, which accounts for the negative quadrants, or the following:

$$\theta = 2 \arctan \left( \frac{r - x}{y} \right)$$

There are several disadvantages to shadow mapping. The relevant ones for us are Aliasing and Shadow Acne:

**Aliasing** occurs when the texture size for the depth map is smaller than the light map, causing shadows to be scaled up and rendered with jagged edges.

**Shadow Acne** occurs when the depth from the depth map is so close to the light map value, that precision errors cause unnecessary shadows to be rendered.

These problems can be mitigated by increasing the size of the shadow map size. However, due to memory and hardware constraints, I will have to find a compromised resolution to balance both artifacting and acuity.

### Soft Shadows

The approach above is used only for calculating hard shadows. However, in real-life scenarios, lights are not modelled as a single particle, but instead emitted from a wide light source. This creates an umbra and penumbra, resulting in soft shadows.

To emulate this in our game, we could calculate penumbra values with various methods, however, due to hardware constraints and simplicity again, I have chosen to use the following simpler method:

1. Sample the depth map multiple times, from various differing angles
2. Sum the results using a normal distribution
3. Blur the final result proportional to the length from the center

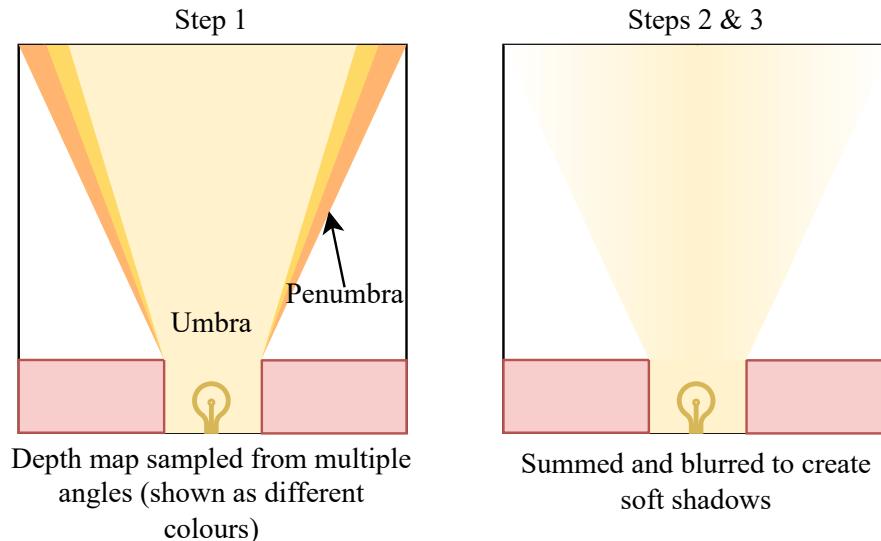

Figure 2.21: Workflow for 2D soft shadows

This method progressively blurs the shadow as the distance from the main shadow (umbra) increases, which results in a convincing estimation while being less computationally intensive.

### 2.2.6 Multithreading

In order to fulfill Objective 7a of a responsive GUI, I will have to employ multi-threading. Since python runs on a single thread natively, code is executed serially, meaning that a time consuming function such as minimax will prevent the running of another GUI-drawing function until it is finished, hence freezing the program. To overcome this, multi-threading can execute both functions in parallel on different threads, meaning the GUI-drawing thread can run while minimax is being computed, and stay responsive. To pass data between threads, since memory is shared between threads, arrays and queues can be used to store results from threads. The following flowchart shows my chosen approach to keep the GUI responsive while minimax is being computed:

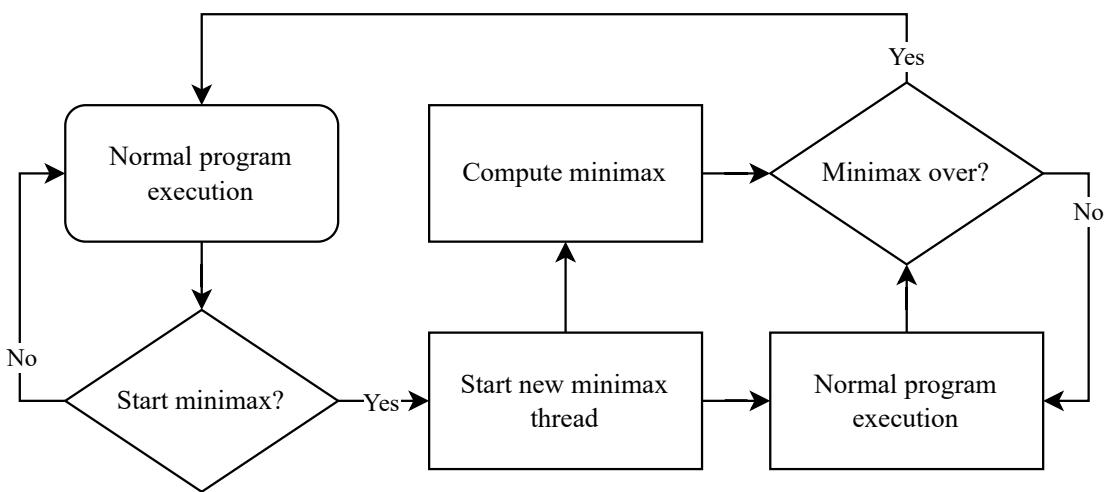

Figure 2.22: Multi-threading for minimax

## 2.3 Data Structures

### 2.3.1 Database

To achieve Objective 3 and stores previous games, I have opted to use a relational database. Choosing between different relational database, I have decided to use SQLite, since it does not require additional server softwars, has good performance with low memory requirements, and adequate for my use cases, with others such as Postgres being overkill.

#### DDL

Only a single entity will be required for my program, a table to store games. The table schema will be defined as follows:

**Table: games**

Field	Key	Data Type	Validation
game_id	Primary	INT	NOT NULL
winner		INT	

cpu_depth	INT	
number_of_moves	INT	NOT NULL
cpu_enabled	BOOL	NOT NULL
moves	TEXT	NOT NULL
initial_board_configuration	TEXT	NOT NULL
time	FLOAT	
created_dt	TIMESTAMP	NOT NULL

Table 2.1: Data table scheme for *games* table

All fields are either generated or retrieved from the board class, with the exception of the moves attribute, which will need to be encoded into a suitable data type such as a string. All attributes are also independent of each other<sup>1</sup>, and so the the table therefore adheres to the third normal form.

To create the entity, a `CREATE` statement like the following can be used:

---

```

1   CREATE TABLE games(
2       id INTEGER PRIMARY KEY,
3       winner INTEGER,
4       cpu_depth INTEGER,
5       time real NOT NULL,
6       moves TEXT NOT NULL,
7       cpu_enabled INTEGER NOT NULL,
8       created_dt TIMESTAMP NOT NULL,
9       number_of_moves INTEGER NOT NULL,
10      initial_fen_string TEXT NOT NULL,
11  )

```

---

Removing an entity can also be done in a similar fashion:

---

```

1   DROP TABLE games

```

---

Migrations are a version control system to track incremental changes to the schema of a database. Since there is no popular SQL Python-binding libraries that support migrations, I will just be using a manual solution of creating python files that represent a change in my schema, defining functions that make use of SQL `ALTER` statements. This allows me to keep track of any changes, and rollback to a previous schema.

## DML

To insert a new game entry into the table, an `INSERT` statement can be used with the provided array, where the appropiate arguments are binded to the correct attribute via `?` placeholders when run.

---

```

1   INSERT INTO games (
2       cpu_enabled,
3       cpu_depth,
4       winner,
5       time,
6       number_of_moves,
7       moves,

```

<sup>1</sup>There is a case to be made for `moves` and `number_of_moves`, however I have included `number_of_moves` to save the computational effort of parsing the moves for every game just to display it on the browser preview section.

---

```

8     initial_fen_string ,
9     created_dt
10    )
11    VALUES  (?, ?, ?, ?, ?, ?, ?, ?, ?)

```

---

Moreover, we will need to fetch the number of total game entries in the table to be displayed to the user. To do this, the aggregate function `COUNT` can be used, which is supported by all SQL databases.

---

```

1   SELECT COUNT(*) FROM games

```

---

## Pagination

When there are a large number of entries in the table, it would be appropriate to display all the games to the user in a paginated form, where they can scroll between different pages and groups of games. There are multiple methods to paginate data, such as using `LIMIT` and `OFFSET` clauses, or cursor-based pagination, but I have opted to use the `ROW_NUMBER()` function.

`ROW_NUMBER()` is a window function that assigns a sequential integer to a query's result set. If I were to query the entire table, each row would be assigned an integer that could be used to check if the row is in the bounds for the current page, and therefore be displayed. Moreover, the use of an `ORDER BY` clause enables sorting of the output rows, allowing the user to choose what order the games are presented in based on an attribute such as number of moves. A `PARTITION BY` clause will also be used to group the results base on an attribute such as winner prior to sorting, if the user wants to search for games based on multiple criteria with greater ease.

The start row and end row will be passed as parameters to the placeholders in the SQL statement, calculated by multiplying the page number by the number of games per page.

---

```

1   SELECT * FROM
2     (SELECT ROW_NUMBER() OVER (
3       PARTITION BY attribute1
4         ORDER BY attribute2 ASC
5     ) AS row_num, * FROM games)
6   WHERE row_num >= ? AND row_num <= ?

```

---

## Security

Security measures such as database file permissions and encryption are common for a SQL database. However, since SQLite is a serverless database, and my program runs without any need for an internet connection, the risk of vulnerabilities is greatly reduced. Additionally, the game data stored on my database is frankly inconsequential, so going to great lengths to protect it wouldn't be to best use of my time. Nevertheless, my SQL Python-binding does support the user of placeholders for parameters, thereby addressing the risk of SQL injection attacks.

### 2.3.2 Linked Lists

Another data structure I intend to implement is linked lists. This will be integrated into widgets such as the carousel or multiple icon button widget, since these will contain a variable number of items, and where  $O(1)$  random access is not a priority. Since moving back and forth between nodes is a must for a carousel widget, the linked list will be doubly-linked, with each node containing to its previous and next node. The list will also need to loop, with the next pointer of the last node pointing back to the first node, making it a circular linked list.

The following pseudocode outlines the basic functionality of the linked list:

---

**Algorithm 9** Circular doubly linked list pseudocode

---

```
function INSERT_AT_FRONT(node)
    if head is none then
        head ← node
        node.next ← node.previous ← head
    else
        node.next ← head
        node.previous ← head.previous
        head.previous.next ← node
        head.previous ← node

        head ← node
    end if
end function
```

**Require:**  $\text{LEN}(list) > 0$ 

```
function DATA_IN_LIST(data)
    current_node ← head.next
    while current_node ≠ head do
        if current_node.data = data then
            return True
        end if
        current_node ← current_node.next
    end while
    return False
end function
```

**Require:** Data in list

```
function REMOVE(data)
    current_node ← head
    while current_node.data ≠ data do
        current_node ← current_node.next
    end while

    current_node.previous.next ← current_node.next
    current_node.next.previous ← current_node.previous

    delete current_node
end function
```

---

### 2.3.3 Stack

Being a data structure with LIFO ordering, a stack is used for handling moves in the review screen. Starting with full stack of moves, every move undone pops an element off the stack to be processed. This move is then pushed onto a second stack. Therefore, cycling between moves requires pushing and popping between the two stacks, as shown in Figure 2.23. The same functionality can be achieved using a queue, but I have chosen to use two stacks as it is simpler

to implement, as being able to quickly check the number of items in each will come in handy.

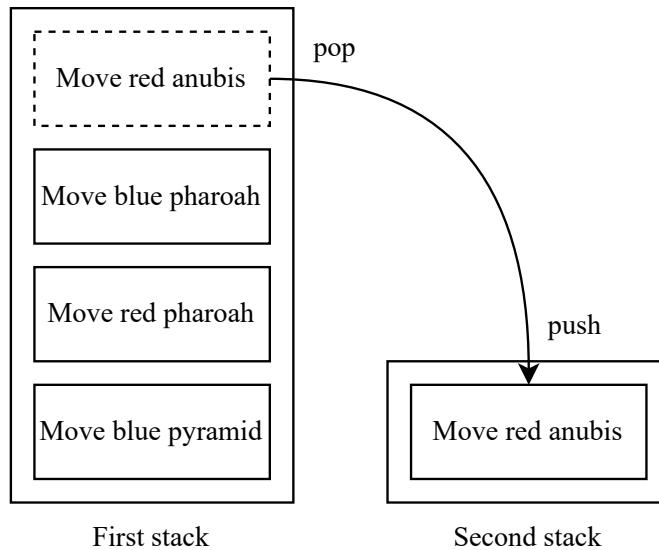

Figure 2.23: *Move red anubis* is undone and pushed onto the second stack

## 2.4 Classes

I will be using an Object-Oriented Programming (OOP) paradigm for my program. OOP reduces repetition of code, as inheritance can be used to abstract repetitive code into a base class, as shown in my widgets implementation. Testing and debugging classes will make my workflow more efficient. This section documents the base classes I am going to implement in my program.

### State

Since there will be multiple screens in my program as demonstrated in Figure 2.1, the State base class will be used to handle the logic for each screen. For each screen, void functions will be inherited and overwritten, each containing their own logic for that specific screen. For example, all screens will call the startup function in Table 2.2 to initialise variables needed for that screen. This polymorphism approach allows me to use another Control class to enable easy switching between screens, without worrying about the internal logic of that screen. Virtual methods also allow methods such as `draw` to be abstracted to the State superclass, reducing code in the inherited subclasses, while allowing them to override the methods and add their own logic.

Method Name	Description
startup	Initialise variables and functions when state set as displayed screen
cleanup	Cleanup any variables and functions when state removed from screen
draw	Draw to display
update	Update any variables for every game tick
handle_resize	Scale GUI when window resized
get_event	Receive pygame events as argument and process them

Table 2.2: Methods for State class

## Widget

I will be implementing my own widget system for creating the game GUI. This allows me to fully customise all graphical elements on the screen, and also create a resizing system that adheres to Objective 7a. The default pygame rescaling options also simply resize elements without accounting for aspect ratios or resolution, and I could not find a library that suits my needs. Having a bespoke GUI implementation also justifies my use of Pygame over other Python frameworks.

I will be utilising the Pygame sprite system for my GUI. All GUI widgets will be subclasses inheriting from the base Widget class, which itself is a subclass of the Pygame sprite class. Since Pygame sprites are drawn via a spritegroup class, I will also have to create a custom subclass inheriting that as well. As with the State class, polymorphism will allow the spritegroup class to render all widgets regardless of their functionality. Each widget will override their base methods, especially the draw (set\_image) method, for their own needs. Additionally, I will use getter and setter methods, used with the `@property` decorator in python, to compute attributes mainly used for resizing widgets. This allows me to expose common variables, and to reduce code repetition.

Method Name	Description
set_image	Render widget to internal image attribute for pygame sprite class
set_geometry	Set position and size of image
set_screen_size	Set screen size for resizing purposes
get_event	Receives pygame events and processes them
screen_size*	Returns screen size in pixels
position*	Returns topleft of widget rect
size*	Returns size of widget in pixels
margin*	Returns distance between border and actual widget image
border_width*	Returns border width
border_radius*	Returns border radius for rounded corners
font_size*	Returns font size for text-based widgets

\* represents getter method / property

Table 2.3: Methods for Widget class

I will also employ multiple inheritance to combine different base class functionalities together. For example, I will create a pressable base class, designed to be subclassed along with the widget class. This will provide attributes and methods for widgets that support clicking and dragging. Following Python's Method Resolution Order (MRO), additional base classes should be referenced first, having priority over the base Widget class.

Method Name	Description
get_event	Receives Pygame events and sets current state accordingly
set_state	Sets current Pressable state, called by <code>get_event</code>
set_colours	Set fill colour according to widget Pressable state
current_state*	Returns current Pressable state (e.g. hovered, pressed etc.)

---

**Method Name | Description**

---

---

 \* represents getter method / property
 

---

Table 2.4: Methods for example Pressable class

**Game**

For my game screen, I will be utilising the Model-View-Controller architectural pattern (MVC). MVC defines three interconnected parts, the model processing information, the view showing the information, and the controlling receiving user inputs and connecting the two. This will allow me to decompose the development process into individual parts for the game logic, graphics and user input, speeding up the development process and making testing easier. It also allows me to implement multiple views, for the pause and win screens as well. For MVC, I will have to implement a game model class, a game controller class, and three classes for each view (game, pause, win). Using aggregation, these will be initially connected and handled by the game state class. For the following methods, I have only showed those pertinent to the MVC pattern:

<b>Method Name</b>	<b>Description</b>
get_event	Receives Pygame events and passes them onto the correct part's event handler
handle_game_event	Receives events and notifies the game model and game view
handle_pause_event	Receives events and notifies the pause view
handle_win_event	Receives events and notifies the win view
...	...

Table 2.5: Methods for Controller class

<b>Method Name</b>	<b>Description</b>
process_model_event	Receives events from the model and calls the relevant method to display that information
convert_mouse_pos	Sends controller class information of widget under mouse
draw	Draw information to display
handle_resize	Scale GUI when window resized
...	...

Table 2.6: Methods for View class

<b>Method Name</b>	<b>Description</b>
register_listener	Subscribes method on view instance to an event type, so that the method receives and processes that event everytime <code>alert_listener</code> is called
alert_listener	Sends event to all subscribed instances
toggle_win	Sends event for win view
toggle_pause	Sends event for pause view
...	...

**Method Name | Description**

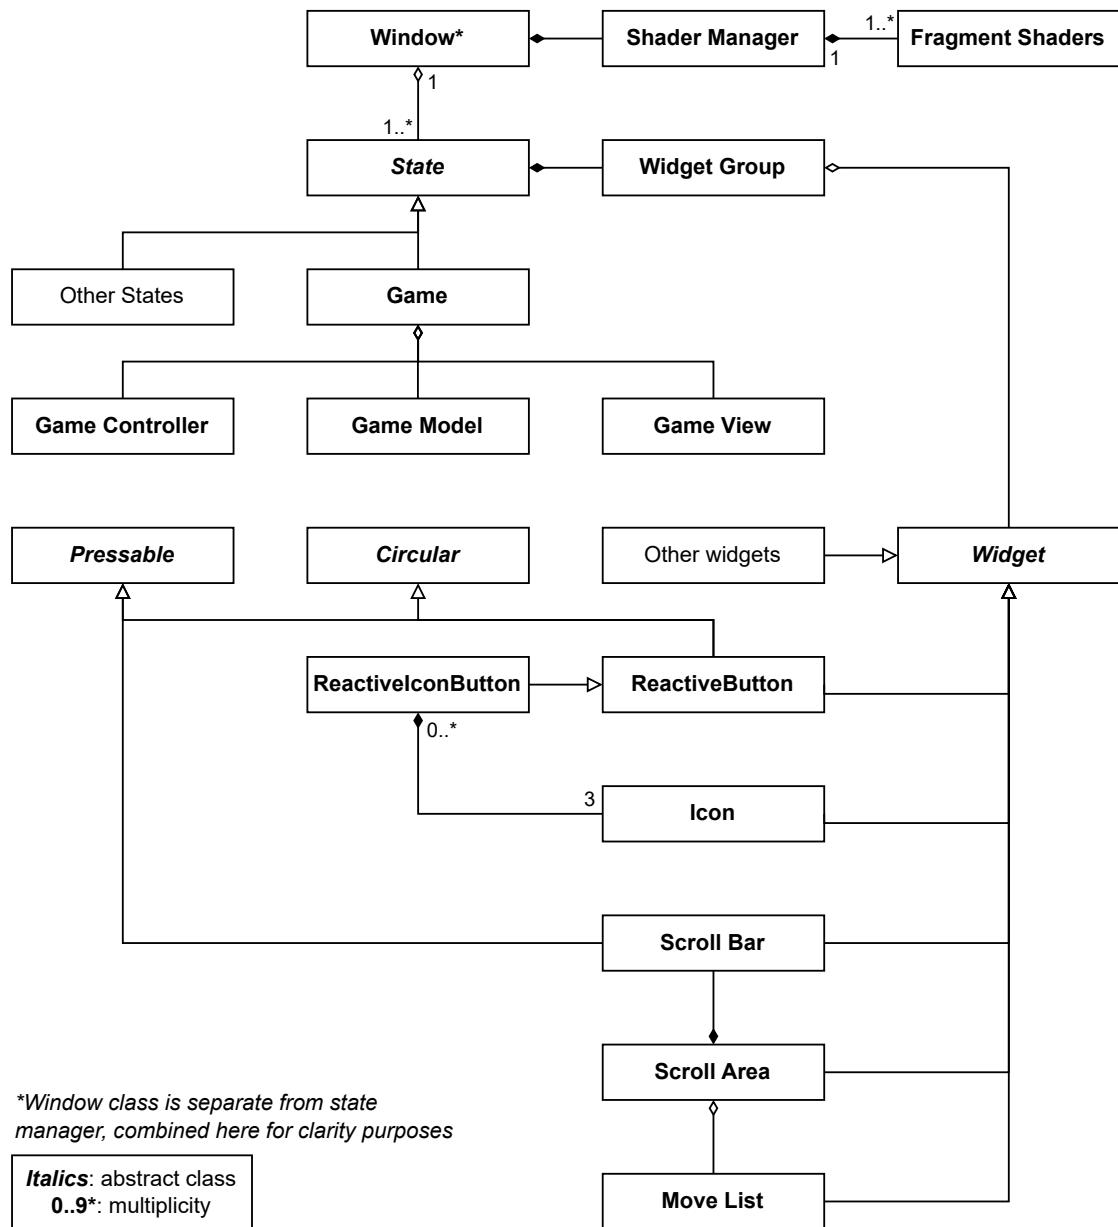

---

Table 2.7: Methods for Model class

**Shaders**

To use ModernGL with Pygame, I have created classes for each fragment shader, controlled by a main shader manager class. The fragment shader classes will rely on composition: The shader manager creates the fragment shader class; Every fragment shader class takes their shader manager parent instance as an argument, and runs methods on it to produce the final output.

## 3.2 Summary of Complexity

- Minimax improvements (3.6.2 and 3.6.3 and 3.6.4)
- Shadow mapping and coordinate transformations (3.9.3)
- Recursive Depth-First Search tree traversal (3.3.4 and 3.6.1)
- Circular doubly-linked list and stack (3.4.3 and 3.7.1)
- Multipass shaders and gaussian blur (3.9.2)
- Aggregate and Window SQL functions (3.8.2)
- OOP techniques (3.4.3 and 3.4.4)
- Multithreading (3.3.2 and 3.6.6)
- Bitboards (3.5.5)
- Zobrist hashing (3.6.7)
- (File handling and JSON parsing) (3.3.3)
- (Dictionary recursion) (3.3.4)
- (Dot product) (3.3.3 and 3.9.2)

## 3.3 Overview

### 3.3.1 Main

The file `main.py` is run by the root file `run.py`. Here resources-intensive classes such as the state and asset files are initialised, while the program displays a loading screen to hide the loading process. The main game loop is then executed.

`main.py`

```

1 from sys import platform
2 # Initialises Pygame
3 import data.setup
4
5 # Windows OS requires some configuration for Pygame to scale GUI continuously
6     # while window is being resized
6 if platform == 'win32':
7     import data.windows_setup as win_setup
8
9 from data.loading_screen import LoadingScreen
10
11 states = [None, None]
12
13 def load_states():
14     """
15         Initialises instances of all screens, executed on another thread with results
16         being stored to the main thread by modifying a mutable such as the states list
17     """
18     from data.control import Control
19     from data.states.game.game import Game
      from data.states.menu.menu import Menu

```

```

20     from data.states.settings.settings import Settings
21     from data.states.config.config import Config
22     from data.states.browser.browser import Browser
23     from data.states.review.review import Review
24     from data.states.editor.editor import Editor
25
26     # Initialise dictionary containing each screen in the game, referenced in
27     # Control class by the current state's 'next' and 'previous' attributes,
28     # corresponding to a key in this dictionary
29     state_dict = {
30         'menu': Menu(),
31         'game': Game(),
32         'settings': Settings(),
33         'config': Config(),
34         'browser': Browser(),
35         'review': Review(),
36         'editor': Editor()
37     }
38
39     app = Control()
40
41     states[0] = app
42     states[1] = state_dict
43
44 def main():
45     """
46     Executed by run.py, starts main game loop
47     """
48     app, state_dict = states
49
50     if platform == 'win32':
51         win_setup.set_win_resize_func(app.update_window)
52
53     app.setup_states(state_dict, 'menu')
54     app.main_game_loop()

```

### 3.3.2 Loading Screen

Multithreading is used to separate the loading screen GUI from the resources intensive actions in `main.py`, to keep the GUI responsive. The easing function `easeOutBack` is also used to animate the logo.

`loading_screen.py`

```

1 import pygame
2 import threading
3 import sys
4 from pathlib import Path
5 from data.helpers.load_helpers import load_gfx, load_sfx
6 from data.managers.window import window
7 from data.managers.audio import audio
8
9 FPS = 30
10 start_ticks = pygame.time.get_ticks()
11 logo_gfx_path = (Path(__file__).parent / '../resources/graphics/gui/icons/logo/
12     logo.png').resolve()
12 sfx_path_1 = (Path(__file__).parent / '../resources/sfx/loading_screen/
13     loading_screen_1.wav').resolve()

```

```

13 sfx_path_2 = (Path(__file__).parent / '../resources/sfx/loading_screen/
14     loading_screen_2.wav').resolve()
15
16 def easeOutBack(progress):
17     """
18         Represents a cubic function for easing the logo position.
19         Starts quickly and has small overshoot, then ends slowly.
20
21     Args:
22         progress (float): x-value for cubic function ranging from 0-1.
23
24     Returns:
25         float:  $2.70x^3 + 1.70x^2 + 0x + 1$ , where x is time elapsed.
26     """
27     c2 = 1.70158
28     c3 = 2.70158
29
30     return c3 * ((progress - 1) ** 3) + c2 * ((progress - 1) ** 2) + 1
31
32 class LoadingScreen:
33     def __init__(self, target_func):
34         """
35             Creates new thread, and sets the load_state() function as its target.
36             Then starts draw loop for the loading screen.
37
38         Args:
39             target_func (Callable): function to be run on thread.
40         """
41         self._clock = pygame.time.Clock()
42         self._thread = threading.Thread(target=target_func)
43         self._thread.start()
44
45         self._logo_surface = load_gfx(logo_gfx_path)
46         self._logo_surface = pygame.transform.scale(self._logo_surface, (96, 96))
47         audio.play_sfx(load_sfx(sfx_path_1))
48         audio.play_sfx(load_sfx(sfx_path_2))
49
50         self.run()
51
52     @property
53     def logo_position(self):
54         duration = 1000
55         displacement = 50
56         elapsed_ticks = pygame.time.get_ticks() - start_ticks
57         progress = min(1, elapsed_ticks / duration)
58         center_pos = ((window.screen.size[0] - self._logo_surface.size[0]) / 2, (
59             window.screen.size[1] - self._logo_surface.size[1]) / 2)
60
61         return (center_pos[0], center_pos[1] + displacement - displacement *
62             easeOutBack(progress))
63
64     @property
65     def logo_opacity(self):
66         return min(255, (pygame.time.get_ticks() - start_ticks) / 5)
67
68     @property
69     def duration_not_over(self):

### 3.4.3 Widget Bases

Widget bases are used as the base classes for my widgets system. They contain both attributes and getter methods that provide both basic functionalities such as size and position, and abstract methods to be overridden. These bases are designed to be used with **multiple inheritance**, where multiple bases can be combined to add functionality to the final widget. **Encapsulation** also allows me to simplify interactions between widgets, as using getter methods instead of protected attributes allows me to add logic while accessing an attribute, such as in `widget.py`, where the logic to fetch the parent surface instead of the windows screen is hidden within the base class.

#### Widget

All widgets are a subclass of the `Widget` class.

`widget.py`

```

1 import pygame
2 from data.utils.constants import SCREEN_SIZE

```

```

3  from data.managers.theme import theme
4  from data.utils.assets import DEFAULT_FONT
5
6  DEFAULT_SURFACE_SIZE = SCREEN_SIZE
7  REQUIRED_KWARGS = ['relative_position', 'relative_size']
8
9  class _Widget(pygame.sprite.Sprite):
10     def __init__(self, **kwargs):
11         """
12             Every widget has the following attributes:
13
14             surface (pygame.Surface): The surface the widget is drawn on.
15             raw_surface_size (tuple[int, int]): The initial size of the window screen,
16             remains constant.
17             parent (_Widget, optional): The parent widget position and size is
18             relative to.
19
20             Relative to current surface:
21             relative_position (tuple[float, float]): The position of the widget
22             relative to its surface.
23             relative_size (tuple[float, float]): The scale of the widget relative to
24             its surface.
25
26             Remains constant, relative to initial screen size:
27             relative_font_size (float, optional): The relative font size of the widget
28
29             relative_margin (float): The relative margin of the widget.
30             relative_border_width (float): The relative border width of the widget.
31             relative_border_radius (float): The relative border radius of the widget.
32
33             anchor_x (str): The horizontal anchor direction ('left', 'right', 'center'
34             '').
35             anchor_y (str): The vertical anchor direction ('top', 'bottom', 'center').
36             fixed_position (tuple[int, int], optional): The fixed position of the
37             widget in pixels.
38             border_colour (pygame.Color): The border color of the widget.
39             text_colour (pygame.Color): The text color of the widget.
40             fill_colour (pygame.Color): The fill color of the widget.
41             font (pygame.freetype.Font): The font used for the widget.

180                 Node: The head node.
181
182         return self._head

```

### 3.4.4 Widgets

As described in Section 2.4, each state contains a `WIDGET_DICT` map, which contains and initialises each widget with their own attributes, and provides references to run methods on them in the state code. Each `WIDGET_DICT` is passed into a `WidgetGroup` object, which is responsible for drawing, resizing and handling all widgets for the current state. Below is a list of all the widgets I have implemented (See Section B.25):

- BoardThumbnailButton
- MultipleIconButton
- ReactiveIconButton
- BoardThumbnail
- ReactiveButton
- VolumeSlider
- ColourPicker
- ColourButton
- BrowserStrip
- PieceDisplay
- BrowserItem
- TextButton
- IconButton
- ScrollArea
- Chessboard
- TextInput
- Rectangle
- MoveList
- Dropdown
- Carousel
- Switch
- Timer
- Text
- Icon
- (`_ColourDisplay`)
- (`_ColourSquare`)
- (`_ColourSlider`)
- (`_SliderThumb`)
- (`_Scrollbar`)

### CustomEvent

The `CustomEvent` class is used to pass data between states and widgets. An event argument is passed into interactive widgets; When a widget wants to pass data back to the state, it returns the event, and adds any attributes that is required. The state then receives and handles these returned events accordingly.

#### `custom_event.py`

```

1 from data.utils.event_types import GameEventType, SettingsEventType,
   ConfigEventType, BrowserEventType, EditorEventType
2
3 # Required keyword arguments when creating a CustomEvent object with a specific
   EventType
4 required_args = {
5     GameEventType.BOARD_CLICK: ['coords'],

```

```

6     GameEventType.ROTATE_PIECE: ['rotation_direction'],
7     GameEventType.SET LASER: ['laser_result'],
8     GameEventType.UPDATE_PIECES: ['move_notation'],
9     GameEventType.TIMER_END: ['active_colour'],
10    GameEventType.PIECE_DROP: ['coords', 'piece', 'colour', 'rotation', 'remove_overlay'],
11    SettingsEventType.COLOUR_SLIDER_SLIDE: ['colour'],
12    SettingsEventType.PRIMARY_COLOUR_PICKER_CLICK: ['colour'],
13    SettingsEventType.SECONDARY_COLOUR_PICKER_CLICK: ['colour'],
14    SettingsEventType.Dropdown_CLICK: ['selected_word'],
15    SettingsEventType.VOLUME_SLIDER_CLICK: ['volume', 'volume_type'],
16    SettingsEventType.SHADER_PICKER_CLICK: ['data'],
17    SettingsEventType.PARTICLES_CLICK: ['toggled'],
18    SettingsEventType.OPENGL_CLICK: ['toggled'],
19    ConfigEventType.TIME_TYPE: ['time'],
20    ConfigEventType.FEN_STRING_TYPE: ['time'],
21    ConfigEventType.CPU_DEPTH_CLICK: ['data'],
22    ConfigEventType.PVC_CLICK: ['data'],
23    ConfigEventType.PRESET_CLICK: ['fen_string'],
24    BrowserEventType.BROWSER_STRIP_CLICK: ['selected_index'],
25    BrowserEventType.PAGE_CLICK: ['data'],
26    EditorEventType.PICK_PIECE_CLICK: ['piece', 'active_colour'],
27    EditorEventType.ROTATE_PIECE_CLICK: ['rotation_direction'],
28 }
29
30 class CustomEvent():
31     def __init__(self, type, **kwargs):
32         self.__dict__.update(kwargs)

```

## ColourSlider

The ColourSlider widget is instanced in the ColourPicker class. It provides a slider for changing between hues for the colour picker, using the functionality of the SliderThumb class.

colour\_slider.py

### 3.5.2 View

As described in Section 2.4, the view class is responsible for displaying changes to information regarding the gameplay. The `process_model_event` procedure is registered with the model class, which executes it whenever the display needs to be updated (e.g. piece move), and the appropriate handling function within the view class is called by mapping the event type to the corresponding handler function.

`game_view.py`

## 3.6 CPU

This section includes my implementation for the CPU engine run on minimax, including its various improvements and accessory classes.

Every CPU engine class is a subclass of a `BaseCPU` abstract class, and therefore contains the same attribute and method names. This means **polymorphism** can be used again to easily to test and vary the difficulty by switching out which CPU engine is used.

The method `find_move` is called by the CPU thread. `search` is then called recursively to traverse the minimax tree, and find an optimal move. The move is then return to `find_move` and passed and run with the callback function. A `stats` dictionary is also created in the base class, used to collect information for each search.

### 3.6.1 Minimax

As described in Section 2.2.1, the minimax engine uses **DFS** to traverse the game tree and evaluate node accordingly, by **recursively** calling the `search` function.

## minimax.py

```

1 from random import choice
2 from data.states.game.cpu.base import BaseCPU
3 from data.utils.enums import Score, Colour
4
5 class MinimaxCPU(BaseCPU):
6     def __init__(self, max_depth, callback, verbose=False):
7         super().__init__(callback, verbose)
8         self._max_depth = max_depth
9
10    def find_move(self, board, stop_event):
11        """

92                 break
93
94     return min_score, best_move
```

### 3.6.3 Transposition Table

For adding transposition table functionality to my other engine classes, as described in Section 2.2.2, I have decided to use a mixin design architecture. This allows me to **reuse code** by adding mixins to many different classes, and inject additional transposition table methods and functionality into other engines.

## transposition\_table.py

```
1 from data.states.game.cpu.transposition_table import TranspositionTable
2 from data.states.game.cpu.engines.alpha_beta import ABMinimaxCPU
3
4 class TranspositionTableMixin:
5     def __init__(self, *args, **kwargs):
6         super().__init__(*args, **kwargs)
7         self._table = TranspositionTable()
8

127     else:
128         return 0

```

### 3.6.6 Multithreading

As described in Section 2.2.6, when the game starts, a `CPUThread` object is created with the selected CPU. The `start` method is called whenever it is the CPU's turn, passing the board as an argument to work on. Each run is also given a random ID, to ensure that only the right search is able to be forcibly terminated early. Using **multithreading** allows the game MVC to continue running smoothly while the CPU calculates its moves on a separate thread.

`cpu_thread.py`

```

1 import threading
2 import time
3 from data.managers.logs import initialise_logger
4
5 logger = initialise_logger(__name__)
6
7 class CPUThread(threading.Thread):
8     def __init__(self, cpu, verbose=False):
9         super().__init__()
10        self._stop_event = threading.Event()
11        self._running = True
12        self._verbose = verbose
13        self.daemon = True
14
15        self._board = None
16        self._cpu = cpu
17        self._id = None
18
19    def kill_thread(self):
20        """
21            Kills the CPU and terminates the thread by stopping the run loop.
22        """
23        self.stop_cpu(force=True)
24        self._running = False
25
26    def stop_cpu(self, id=None, force=False):
27        """
28            Kills the CPU's move search.
29
30            Args:

()}' idling...)

```

### 3.6.7 Zobrist Hashing

As described in Section 2.2.2, the `ZobristHasher` class provides methods to successively **hash** a given board for every move played, with the initial hash being generated in the `Board` class.

`zobrist_hasher.py`

```

1  from random import randint
2  from data.helpers.bitboard_helpers import bitboard_to_index
3  from data.utils.enums import Piece, Colour, Rotation
4
5  # Initialise random values for each piece type on every square
6  # (5 x 2 colours) pieces + 4 rotations, for 80 squares
7  zobrist_table = [[randint(0, 2 ** 64) for i in range(14)] for j in range(80)]
8  # Hash for when the red player's move
9  red_move_hash = randint(0, 2 ** 64)
10
11 # Maps piece to the correct random value
12 piece_lookup = {
13     Colour.BLUE: {
14         piece: i for i, piece in enumerate(Piece)
15     },
16     Colour.RED: {
17         piece: i + 5 for i, piece in enumerate(Piece)
18     },
19 }
20
21 # Maps rotation to the correct random value
22 rotation_lookup = {
23     rotation: i + 10 for i, rotation in enumerate(Rotation)
24 }
25
26 class ZobristHasher:
27     def __init__(self):
28         self.hash = 0
29
30     def get_piece_hash(self, index, piece, colour):

```

```

31     """
32     Gets the random value for the piece type on the given square.

78                 bitboard (int): The bitboard representation of the square.
79                 rotation (Rotation): The rotation on the square.
80
81             index = bitboard_to_index(bitboard)
82             rotation_hash = self.get_rotation_hash(index, rotation)
83             self.hash ^= rotation_hash
84
85             def apply_red_move_hash(self):
86                 """
87                     Applies the Zobrist hash for the red player's move.
88
89                     self.hash ^= red_move_hash

```

### 3.6.8 Cache

As described in Section 2.2.2, the `TranspositionTable` class maintains an internal hash map to store already evaluated board positions. Since I have chosen to use a dictionary instead of an array, the Zobrist hash for the board can be used as the keys for the dictionary as is, as it doesn't correspond to the index position as will be the case if I use an array.

`transposition_table.py`

```

1 from data.utils.enums import TranspositionFlag
2
3 class TranspositionEntry:
4     def __init__(self, score, move, flag, hash_key, depth):
5         self.score = score
6         self.move = move
7         self.flag = flag
8         self.hash_key = hash_key
9         self.depth = depth
10
11 class TranspositionTable:
12     def __init__(self, max_entries=100000):
13         self._max_entries = max_entries
14         self._table = dict()
15
16     def calculate_entry_index(self, hash_key):
17         """
18             Gets the dictionary key for a given Zobrist hash.
19
20         Args:
21             hash_key (int): A Zobrist hash.
22
23         Returns:
24             int: Key for the given hash.
25         """
26
27     return hash_key
28
29     def insert_entry(self, score, move, hash_key, depth, alpha, beta):
30         """
31             Inserts an entry into the transposition table.
32
33         Args:
34             score (int): The evaluation score.
35             move (Move): The best move found.
36             hash_key (int): The Zobrist hash key.
37             depth (int): The depth of the search.
38             alpha (int): The upper bound value.
39             beta (int): The lower bound value.
40
41         Raises:
42             Exception: Invalid depth or score.
43
44         if depth == 0 or alpha < score < beta:

91
92         return None, None

```

### 3.7 States

To switch between different screens, I have decided to use a state machine design pattern. This ensures that there is only one main game loop controlling movement between states, handled with the `Control` object. All `State` object contain a `next` and `previous` attribute to tell the `Control` class which screen to switch to, which also calls all `State` methods accordingly.

The `startup` method is called when switched to a new state, and `cleanup` when exiting. Within the `startup` function, the state widgets dictionary is passed into a `WidgetGroup` object. The `process_event` method is called on the `WidgetGroup` every frame to process user input, and handle the returned events accordingly. The `WidgetGroup` object can therefore be thought of as a controller, and the state as the model, and the widgets as the view.

### 3.7.1 Review

The `Review` state uses this logic to allow users to scroll through moves in their past games. All moves are stored in two `stacks`, as described in Section 2.3.3, and exchanged using `pop` and `append` (`push`) methods.

```

## 3.8 Database

This section outlines my database implementation using the Python module sqlite3.

### 3.8.1 DDL

As mentioned in Section 2.3.1, the `migrations` directory contains a collection of Python scripts that edit the game table schema. The files are named with a description of their changes and datetime for organisational purposes.

`create_games_table_19112024.py`

```

1 import sqlite3
2 from pathlib import Path
3
4 database_path = (Path(__file__).parent / '../database.db').resolve()
5
6 def upgrade():
7     """
8         Upgrade function to create games table.
9     """
10    connection = sqlite3.connect(database_path)
11    cursor = connection.cursor()
12
13    cursor.execute('''
14        CREATE TABLE games(
15            id INTEGER PRIMARY KEY,
16            cpu_enabled INTEGER NOT NULL,
17            cpu_depth INTEGER,
18            winner INTEGER,
19            time_enabled INTEGER NOT NULL,
20            time REAL,
21            number_of_ply INTEGER NOT NULL,
22            moves TEXT NOT NULL
23        )
24    ''')
25
26    connection.commit()
27    connection.close()
28
29 def downgrade():
30     """
31         Downgrade function to revert table creation.
32     """
33    connection = sqlite3.connect(database_path)
34    cursor = connection.cursor()
35

```

```

36     cursor.execute('''
37         DROP TABLE games
38     ''')
39
40     connection.commit()
41     connection.close()
42
43 upgrade()
44 # downgrade()

```

Using the `ALTER` command allows me to rename table columns.

```

change_fen_string_column_name_23122024.py

1 import sqlite3
2 from pathlib import Path
3
4 database_path = (Path(__file__).parent / '../database.db').resolve()
5
6 def upgrade():
7     """
8     Upgrade function to rename fen_string column.
9     """
10    connection = sqlite3.connect(database_path)
11    cursor = connection.cursor()
12
13    cursor.execute('''
14        ALTER TABLE games RENAME COLUMN fen_string TO final_fen_string
15    ''')
16
17    connection.commit()
18    connection.close()
19
20 def downgrade():
21     """
22     Downgrade function to revert fen_string column renaming.
23     """
24    connection = sqlite3.connect(database_path)
25    cursor = connection.cursor()
26
27    cursor.execute('''
28        ALTER TABLE games RENAME COLUMN final_fen_string TO fen_string
29    ''')
30
31    connection.commit()
32    connection.close()
33
34 upgrade()
35 # downgrade()

```

### 3.8.2 DML

As described in Section 2.3.1, this file provides functions to help modify the database, with **Aggregate** and **Window** commands used to retrieve the number of rows and sort them to be returned. `database_helpers.py`

```

1 import sqlite3
2 from pathlib import Path
3 from datetime import datetime
4

```

```
5 database_path = (Path(__file__).parent / '../database/database.db').resolve()
6
7 def insert_into_games(game_entry):
8     """
9         Inserts a new row into games table.
10
11     Args:
12         game_entry (GameEntry): GameEntry object containing game information.
13     """
14     connection = sqlite3.connect(database_path, detect_types=sqlite3.
15         PARSE_DECLTYPES)
16     connection.row_factory = sqlite3.Row

## 3.9 Shaders

### 3.9.1 Shader Manager

The `ShaderManager` class is responsible for handling all shader passes, handling the Pygame display, and combining both and drawing the result to the window screen. The class also `inherits` from the `SMPProtocol` class, an `interface` class containing all required `ShaderManager` methods and attributes to aid with syntax highlighting in the fragment shader classes.

Fragment shaders such as `Bloom` are applied by default, and others such as `Ray` are applied during runtime through calling methods on `ShaderManager`, and adding the appropriate fragment shader class to the internal shader pass list.

Each fragment shader is written in GLSL and stored in a `.frag` file, and read into the `ShaderManager` class.

`shader.py`

```

1 from pathlib import Path
2 from array import array

```

```

### 3.9.2 Bloom

The `Bloom` shader effect is a common shader effect giving the illusion of a bright light. It consists of blurred fringes of light extending from the borders of bright areas. This effect can be achieved through obtaining all bright areas of the image, applying a Gaussian blur, and blending the blur additively onto the original image.

My `ShaderManager` class works with this multi-pass shader approach by reading the texture from the last shader's framebuffer for each pass.

#### Extracting bright colours

The `highlight_brightness` fragment shader extracts all colours that are bright enough to exert the bloom effect.

`highlight_brightness.frag`

```

1 # version 330 core
2
3 in vec2 uvs;
4 out vec4 f_colour;
5
6 uniform sampler2D image;
7 uniform float threshold;

```

```

8 uniform float intensity;
9
10 void main() {
11     vec4 pixel = texture(image, uvs);
12     // Dot product used to calculate brightness of a pixel from its RGB values
13     // Values taken from https://en.wikipedia.org/wiki/Relative_luminance
14     float brightness = dot(pixel.rgb, vec3(0.2126, 0.7152, 0.0722));
15     float isBright = step(threshold, brightness);
16
17     f_colour = vec4(vec3(pixel.rgb * intensity) * isBright, 1.0);
18 }

```

## Blur

The `Blur` class implements a two-pass **Gaussian blur**. This is preferably over a one-pass blur, as the complexity is  $O(2n)$ , sampling  $n$  pixels twice, as opposed to  $O(n^2)$ . I have implemented this using the ping-pong technique, with the first pass for blurring the image horizontally, and the second pass for blurring vertically, and the resultant textures being passed repeatedly between two framebuffers.

### `blur.py`

```

1 from data.shaders.protocol import SMProtocol
2 from data.utils.constants import ShaderType
3
4 BLUR_ITERATIONS = 4
5
6 class _Blur:
7     def __init__(self, shader_manager: SMProtocol):
8         self._shader_manager = shader_manager
9
10        shader_manager.create_framebuffer(ShaderType._BLUR)
11
12        shader_manager.create_framebuffer("blurPing")
13        shader_manager.create_framebuffer("blurPong")
14

```

```
=1, intensity=BL00M_INTENSITY)
```

### 3.9.3 Rays

As described in Section 2.2.5, the `ray` shader is applied whenever the sphinx shoots a laser. It simulates a 2D light source, providing pixel perfect shadows, through the shadow mapping technique outlined in Section 2.2.5. The laser demo seen on the main menu screen is also achieved using the Ray shader, by clamping the angle at which it emits light to a narrower range.

### Occlusion

The occlusion fragment shader processes all pixels with a given colour value as being occluding. `occlusion.frag`

```
1 # version 330 core
2
3 in vec2 uvs;
4 out vec4 f_colour;
5
6 uniform sampler2D image;
7 uniform vec3 checkColour;
8
9 void main() {
10     vec4 pixel = texture(image, uvs);
11
12     // If pixel is occluding colour, set pixel to white
13     if (pixel.rgb == checkColour) {
14         f_colour = vec4(1.0, 1.0, 1.0, 1.0);
15     // Else, set pixel to black
16     } else {
17         f_colour = vec4(vec3(0.0), 1.0);
18     }
19 }
```

### Shadowmap

The shadowmap fragment shader takes the occluding texture and creates a 1D shadow map. `shadowmap.frag`

```
1 # version 330 core
2
3 #define PI 3.1415926536;
4
5 in vec2 uvs;
6 out vec4 f_colour;
7
8 uniform sampler2D image;
9 uniform float resolution;
10 uniform float THRESHOLD=0.99;
11
12 void main() {
13     float maxDistance = 1.0;
14
15     for (float y = 0.0 ; y < resolution ; y += 1.0) {
16         //rectangular to polar filter
17         float currDistance = y / resolution;
```

```

19     vec2 norm = vec2(uvs.x, currDistance) * 2.0 - 1.0; // Range from [0, 1] ->
20     [-1, 1]
21     float angle = (1.5 - norm.x) * PI; // Range from [-1, 1] -> [0.5PI, 2.5PI]
22     float radius = (1.0 + norm.y) * 0.5; // Range from [-1, 1] -> [0, 1]
23
24     // coord which we will sample from occlude map
25     vec2 coords = vec2(radius * -sin(angle), radius * -cos(angle)) / 2.0 +
26     0.5;
27
28     // Sample occlusion map
29     vec4 occluding = texture(image, coords);
30
31     // If pixel is not occluding (Red channel value below threshold), set
32     maxDistance to current distance
33     // If pixel is occluding, don't change distance
34     // maxDistance therefore is the distance from the center to the nearest
35     // occluding pixel
36     maxDistance = max(maxDistance * step(occluding.r, THRESHOLD), min(
37     maxDistance, currDistance));
38 }
39
40 f_colour = vec4(vec3(maxDistance), 1.0);
41 }
```

## Lightmap

The lightmap shader checks if a pixel is in shadow, blurs the result, and applies the radial light source.

### lightmap.frag

```

1 # version 330 core
2
3 #define PI 3.14159265
4
5 in vec2 uvs;
6 out vec4 f_colour;

13 uniform sampler2D occlusionMap;
14 uniform sampler2D image;
15
16 vec3 normLightColour = lightColour / 255;
17 vec2 radiansClamp = angleClamp * (PI / 180);
18
19 float sample(vec2 coord, float r) {
20     /*
21     Sample from the 1D distance map.
22
23     Returns:
24     float: 1.0 if sampled radius is greater than the passed radius, 0.0 if not.
25     */
26     return step(r, texture(image, coord).r);
27 }
28
29 void main() {
30     // Cartesian to polar transformation
31     // Range from [0, 1] -> [-1, 1]
```

```

32     vec2 norm = uvs.xy * 2.0 - 1.0;
33     float angle = atan(norm.y, norm.x);
34     float r = length(norm);
35
36     // The texture coordinates to sample our 1D lookup texture
37     // Always 0.0 on y-axis, as the texture is 1D
38     float x = (angle + PI) / (2.0 * PI); // Normalise angle to [0, 1]
39     vec2 tc = vec2(x, 0.0);
40
41     // Sample the 1D lookup texture to check if pixel is in light or in shadow
42     // Gives us hard shadows
43     // 1.0 -> in light, 0.0, -> in shadow
44     float inLight = sample(tc, r);
45     // Clamp angle so that only pixels within the range are in light
46     inLight = inLight * step(angle, radiansClamp.y) * step(radiansClamp.x, angle);
47
48     // Multiply the blur amount by the distance from the center
49     // So that the blurring increases as distance increases
50     float blur = (1.0 / resolution) * smoothstep(0.0, 0.1, r);
51
52     // Use gaussian blur to apply blur effect
53     float sum = 0.0;
54
55     sum += sample(vec2(tc.x - blur * 4.0, tc.y), r) * 0.05;
56     sum += sample(vec2(tc.x - blur * 3.0, tc.y), r) * 0.09;
57     sum += sample(vec2(tc.x - blur * 2.0, tc.y), r) * 0.12;
58     sum += sample(vec2(tc.x - blur * 1.0, tc.y), r) * 0.15;
59
60     sum += inLight * 0.16;
61
62     sum += sample(vec2(tc.x + blur * 1.0, tc.y), r) * 0.15;
63     sum += sample(vec2(tc.x + blur * 2.0, tc.y), r) * 0.12;
64     sum += sample(vec2(tc.x + blur * 3.0, tc.y), r) * 0.09;
65     sum += sample(vec2(tc.x + blur * 4.0, tc.y), r) * 0.05;
66
67     // Mix with the softShadow uniform to toggle degree of softShadows
68     float finalLight = mix(inLight, sum, softShadow);
69
70     // Multiply the final light value with the distance, to give a radial falloff
71     // Use as the alpha value, with the light colour being the RGB values
72     f_colour = vec4(normLightColour, finalLight * smoothstep(1.0, falloff, r));
73 }

```

## Class

The `Rays` class takes in a texture and array of light information, applies the aforementioned shaders, and blends the final result with the original texture.

### `rays.py`

```

1  from data.shaders.classes.lightmap import _Lightmap
2  from data.shaders.classes.blend import _Blend

# Chapter 4

## Testing

### 4.1 Iterative Testing

I have been playtesting the program throughout the development process to find any bugs and fix them accordingly. However, a few issues have required additional measures.

#### 4.1.1 Minimax

Since minimax is recursive algorithm, debugging it has proven a challenge. I have therefore configured the Python `logging` library to help collect information on the minimax tree for every function call.

`base.py`

```
1  def print_stats(self, score, move):
2      """
3          Prints statistics after traversing tree.
4
5          Args:
6              score (int): Final score obtained after traversal.
7              move (Move): Best move obtained after traversal.
8
9          If self._verbose is False:
10              return
11
12          self._stats['time_taken'] = round(1000 * (time.time() - self._stats['
13              time_taken']), 3)
14          self._stats['ms_per_node'] = round(self._stats['time_taken'] / self._stats
15              ['nodes'], 3)
16
17          # Prints stats across multiple lines
18          if self._verbose is True:
19              logger.info(f'\n\n'
20                          f'{self.__str__()} Search Results:\n'
21                          f'{printer.pformat(self._stats)}\n'
22                          f'Best score: {score}    Best move: {move}\n'
23                          )
24
25          # Prints stats in a compacted format
26          elif self._verbose.lower() == 'compact':
27              logger.info(self._stats)
```

```
26     logger.info(f'Best score: {score}    Best move: {move}')
```

Listing 4.1: BaseCPU Method for logging minimax statistics

### 4.1.2 Migrations

To correct errors made to the `games` table, since recreating it would mean deleting all existing games, I have opted to use migrations to fix bugs by editing the table schema, as shown in Section 3.8.1.

## 4.2 Unit Tests

### 4.2.1 Board Evaluator

To test every aspect of the evaluation function, I have set up some unit tests with custom positions using my editor screen. These positions are designed to test every aspect of the evaluation, along with some obviously imbalanced positions to test the overall accuracy of the evaluation function. All positions are set up to give an advantage to the blue player.

Evaluating	FEN string	Score	Passed
Material	<code>sc9/10/10/4paPa4/5Pa4/10/10/9Sa b</code>	124	✓
Position	<code>sc9/4nanana3/10/10/10/4NaNaNa3/10/9Sa b</code>	66	✓
Mobility	See footnote <sup>1</sup>	196	✓
King Safety	<code>sc4fa3pa/10/10/10/10/10/10/5FaPa2Sa b</code>	3	✓
Combined	See footnote <sup>2</sup>	437	✓

Table 4.1: Board evaluator test results

### 4.2.2 CPU

Similarly, to evaluate the strength of my CPU, I have setup some custom positions that I already know the best continuation of, and run each CPU engine on them to test if they can solve it.

Description	FEN string	Best Move	Passed
Mate in 1	<code>sc9/pafa8/Fa9/10/10/10/10/9Sa b</code>	Rotate J3 clockwise	✓
Mate in 1	<code>sc9/10/10/8faRb/8FaRb/10/9Sa b</code>	Move J3 to J2	✓
Mate in 3	<code>sc9/10/10/8Ra1/7FaRafa/8RaRa/9Ra/9Sa b</code>	Move J2 to I1... <sup>3</sup>	✓
Mate in 3	<code>sc5fcnc2/4Pa4Pc/3pb6/2Pc2ra1pb2/10/pb9/7Pa2 /2PdNaFa4Sa b</code>	Move E7 to F7... <sup>4</sup>	✓
Mate in 3	<code>sc2pdfc5/2Ra1ra5/pa3Pc4Rb/pb1rd1Pdra4/7Rd2/3 Ra1Pa4/4Fa5/3PdNaPa3Sa b</code>	Move J6 to J7... <sup>5</sup>	✓

<sup>1</sup>`scpapa7/papapa7/papapa1Pa1Pa1Pa1/10/4Pa1Pa1Pa1/10/4Pa1Pa3/9Sa b`

<sup>2</sup>`scnclfcncpbpb3/pa9/pb1pc1rbpa3Pd/1Pc2Pd4Pc/2Pd1RaRb4/10/7Pa2/2PdNaFaNa3Sa b`

<sup>3</sup>2. Move J4 to J5 3. Move J3 to I2

<sup>4</sup>2. Rotate anticlockwise H8 3. Move F7 to G7

<sup>5</sup>2. Move E7 to F8 3. Move E4 to E5

Description	FEN string	Best Move	Passed
Win Material	s c9/2fa7/5NaPb3/pa2ra1Pd4/3pcnd1pd2Rd/3pc6 /10/8FaSa b	Move F6 to G7... <sup>6</sup>	✓

Table 4.2: Iterative Deepening CPU test results

### 4.2.3 Shadow Mapping

To test the shadow mapping algorithm, I have set up some occluding objects together with a light source. Since visuals are subjective, me and my client have deemed the following results to be adequate.

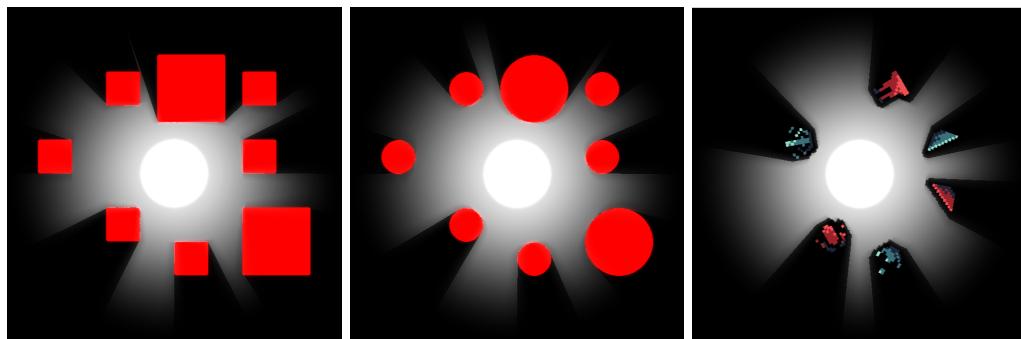

Figure 4.1: Shadow mapping algorithm test (softShadow=0.5, radius=0.5)

## 4.3 Final Tests

### 4.3.1 Objective 1

All laser chess game logic should be properly implemented.

No.	Input	Output	Passed
6	Position piece with non-reflecting side facing laser	Piece is destroyed	✓
1	Laser fires on pyramid	Pyramid reflects laser by 90°	✓
2	Laser fires on scarab	Scarab reflects laser by 90°	✓
3	Laser fires on anubis	Anubis absorbs laser	✓
4	Move piece as blue player	Active colour switches to red player	✓
5	Move piece or rotate piece	Laser fires	✓
6	Fire laser onto pharaoh	Pharaoh is destroyed and opposite colour wins	✓
8	Repeat same position three times	Game displays game over screen	✓

<sup>6</sup>2. Move E4 to E3 3. Move H5 to D4 4. Move J4 to J3

### 4.3.2 Objective 2

Game should process user input correctly.

No.	Input	Output	Passed
8	Click piece	Overlay appears showing selected piece	✓
9	Click piece and click outside board	Overlay disappears showing deselected piece	✓
10	Click piece and click adjacent square	Piece moves to clicked square	✓
11	Click and hold piece and release over adjacent square	Piece moves to adjacent square	✓
12	Click piece and press rotate clockwise button	Piece rotates clockwise	✓
12	Click piece and press rotate anticlockwise button	Piece rotates anticlockwise	✓

### 4.3.3 Objective 3

Save or load game options should be implemented.

No.	Input	Output	Passed
13	Click on copy FEN string button in editor or browser screen	Position formatted as FEN string copied to clipboard	✓
14	Click browser button	Program shows list of past games to be scrolled through	✓
1	Select time as sorting criterion	Browser updates to show most recent games played	✓
1	Select descending as ordering criterion	Browser updates to show oldest games played	✓
1	Click on previous game and click delete button	Selected game is deleted and disappears	✓
1	Click on previous game and click review button	Game is displayed in review screen	✓
12	Enter review screen	Program displays list of past moves, winner and move number	✓
11	Click on previous button in review screen	Board undoes move	✓
11	Click on next move button in review screen	Board applies move	✓

### 4.3.4 Objective 4

Other board game requirements should be implemented.

No.	Input	Output	Passed
13	Click on draw button	Game ends and shows draw result	✓
14	Click on resign button	Game ends and shows win result for opponent	✓
15	Click on timer button to enable timer	Timers appear on the left and decrement every second	✓
16	Pause the game	Timer stops decrementing	✓
17	Allow timer to run to zero	Game ends and shows win result for opponent	✓

#### 4.3.5 Objective 5

Game settings and config should be customisable.

No.	Input	Output	Passed
17	Click on CPU button	Opponent moves are played by minimax CPU	✓
17	Click on timer button to disable timer	Timer is not shown	✓
17	Click on timer duration and input new number	Timer starts with inputted duration	✓
21	Press starting colour button to set starting colour to red	Starting move is played by the red player	✓
22	Enter valid FEN string into text input	Board preview updates and game starts with inputted board layout	✓
23	Enter invalid FEN string into text input	Error message appears	✓
23	In editor screen, select piece and click on square	Piece placed on square	✓
12	Click piece and press rotate clockwise button	Piece rotates clockwise	✓
12	Click piece and press rotate anticlockwise button	Piece rotates anticlockwise	✓
23	Click empty button	All pieces disappear (except sphinxes)	✓
23	Click reset button	Board resets to initial layout	✓
23	Click confirm button	Switches to config screen with edited FEN string and board preview	✓
23	Click return button	Switches to config screen with changes discarded	✓
17	In settings screen, change primary board colour to blue	Alternating board squares appear blue	✓
17	Change secondary board colour to red	Board squares alternate blue and red	✓
18	Change display mode to fullscreen	Application window enlarges to fill entire screen	✓

No.	Input	Output	Passed
18	Slide volume thumb to right and left of slider	Music increases and decreases in volume	✓
20	Toggle particle and shader switches to off position	Particles and shaders are disabled after program restart	✓

#### 4.3.6 Objective 6

Game UI should improve player experience.

No.	Input	Output	Passed
18	Click on piece	Highlight overlay is rendered on selected square	✓
18	Click on piece	Circular overlays are rendered on surrounding unoccupied squares	✓
18	Fire laser on piece	Audio cue plays and piece is visibly destroyed	✓
18	Fire laser on piece	Piece appears on opponent's piece display	✓
18	Play a game	Status text updates to display the active player's colour or CPU status	✓
18	Hover over board, hold the mouse button, click on text input widget	Mouse cursor switches between arrow, open hand, closed hand and I-beam icons	✓

#### 4.3.7 Objective 7

GUI design should be functional and display concise information.

No.	Input	Output	Passed
27	Click the play button on the main menu screen	Program switches to the config screen	✓
27	Click the browser button on the main menu screen	Program switches to the browser screen	✓
27	Click the settings button on the main menu screen	Program switches to the settings screen	✓
28	Click main menu button	Program switches to the menu screen	✓
29	Click help button	Help overlay appears	✓
29	Click quit button	Program quits	✓
31	Drag program window	Program continues running	✓
30	Resize program window	GUI Widgets resize continuously	✓

# Chapter 5

## Evaluation

Overall, I believe that my final program has effectively achieved the requirements set out by my client. It is a step up to current alternatives that I have found online, and seems to be a solid choice for anyone wanting to play laser chess digitally.

### 5.1 Objectives

#### 5.1.1 Objective 1

All laser chess game logic should be properly implemented. Refer to Figure A.4.

Both the play and review screens display a 10x8 laser chess board. The laser fires automatically after every move, and follows the trajectory as directed by the pieces, destroying any that are facing the wrong way (Objectives 1f, 1g). All the pieces reflect and are destroyed by the laser correctly, with the colour to move alternating between both players (Objectives 1a-1e). The game ends when a player either draws or resigns, has their pharaoh destroyed, or reaches three-fold repetition (Objectives 1h, 1i).

The game logic runs successfully, Objective 1 is fulfilled.

#### 5.1.2 Objective 2

Game should process user input correctly. Refer to Figure A.4.

Players can select, move and rotate pieces on their respective turns, through clicking squares, rotate buttons or by dragging the pieces (Objectives 2a, 2c, 2d, 2e). The game cancels any invalid moves (Objective 2b). When a player holds down on a piece, the piece is moved through the drag-and-drop mechanism, and is released on the hovered square (Objective 2d).

Objective 2 is fulfilled.

#### 5.1.3 Objective 3

Save or load game options should be implemented. Refer to Figures A.6 and A.7.

In the browser screen, users can scroll through all previous games, with the option to delete or review them, or copy their FEN string (Objectives 3c, 3e, 3f). Games can be sorted, and pages of games can be scrolled through (Objective 3d). The game positions are encoded using a custom FEN string format, and games are saved as rows in a local SQLite database table (Objectives 3a, 3b). In the review screen, users can scroll through all the moves of a previous game (Objective

3h). The right side bar displays information such as the winner and move number, and the timer, pieces and move list updates accordingly (Objective 3g).

Objective 3 is fulfilled. A possible improvement would be to add the option of loading up a position to resume playing straight from the review screen. This would be a convenient feature, but is not a priority, as users can currently copy the FEN string from the browser screen to the config screen and load the position there as a current alternative.

#### 5.1.4 Objective 4

Other board game requirements should be implemented. Refer to Figure A.4.

In addition to the core game mechanics, other ancillary aspects are added as well. Timers can be enabled and disabled, decrement correctly, and end the game when they run out (Objectives 4c, 4d). Buttons also exist for drawing and resigning the game (Objectives 4a, 4b).

Objective 4 is fulfilled.

#### 5.1.5 Objective 5

Game settings and config should be customisable. Refer to Figures A.2 and A.3 and A.5.

In the settings screen, the user can change settings to toggle the volume, fullscreen, board colours, particles and shaders (Objectives 5i, 5j). All settings update correctly, and are saved to a local JSON file when the settings screen is exited. The game configurations are changed in the config screen. Here, users can change the game's starting colour, configure timer settings, change to the CPU player and specify the difficulty, select a board preset, or create a custom board layout through the editor screen (Objectives 5a-5c). The editor screen comes with all the basic operations of placing pieces, rotating pieces, and erasing and dragging them, but also helpful buttons to erase or reset the board (Objectives 5f-5h). Another method to change the board layout is through inputting a FEN string, and the board either updates or displays an error message depending on the validity of the string (Objectives 5d, 5e).

Objective 5 is fulfilled.

#### 5.1.6 Objective 6

Game UI should improve player experience. Refer to Figure A.4.

Indicators are present to highlight the selected square and any adjacent squares that it can be moved to (Objectives 6a, 6b). Audio cues also improve the immersiveness of the game, as well as the laser visuals and particle effects (Objective 6c). The mouse cursor was also modified to help user-friendliness, by changing its icon depending on the current action being performed, for example, a closed hand icon for grabbing a piece (Objective 6g). The move list and status message widgets are positioned on the right of the game screen, update accordingly and provide information on the game (Objectives 6e, 6f). The piece display also correctly updates to show all destroyed pieces (Objective 6d).

Objective 6 is fulfilled.

#### 5.1.7 Objective 7

GUI design should be functional and display concise information. Refer to Figure A.1.

I have created most of the custom pixel art and icon graphics to improve the game's visual and attempt to make it more engaging (Objective 7c) There are currently 7 screens in the game: menu, settings, config, editor, game, browser and review, each containing their own eponymous function (Objective 7b). Most screens also contain both the main menu button and help button.

Clicking the menu button switches to the main menu screen, and clicking the help button shows an overlay displaying the functionality of drawn widgets (Objective 7d). Shaders are also used to improve the game's visuals, such as by giving the laser a light-emitting effect, but is also used to draw all the backgrounds (Objective 7e). The program runs well, with moments involving heavy calculation being helped by multithreading, and also resizes seamlessly (Objective 7a, 7f).

Objective 7 is fulfilled. Although the program runs smoothly on my device, some fragment shaders are computationally expensive, and may therefore affect the performance. I have attempted to resolve this by adding the option to disable shaders, however, a better solution would be to optimise the expensive shader code, for example, by manually calculating masks using widget dimensions instead of the in-built Pygame mask function. Additionally, working on Windows, I did not bundle the program to MacOS or Linux. Although this was not a priority, having access to other OS testing environments would've widened access to the game.

## 5.2 Client Feedback

The following interview was conducted after Mr Myslov received and played through the program.

**Q:** Did the final product meet your expectations?

**A:** Yes, it certainly did. The game plays perfectly, I could move, rotate all the pieces as expected, and the laser works well. All the features I requested for were there, and the visuals were also more than I expected and welcome.

---

**Q:** What improvements could be made to the program?

**A:** I found that it was difficult for my laptop to run the program without sacrificing some of the visuals. I also found your FEN string implementation confusing, as there was no guidance on what the characters meant, or what the string represented. Figuring out how to play the game was also initially difficult, as I didn't know what the pieces represented through their icons, or how they would deal with the laser.

---

**Q:** What other aspects would you like to have been added?

**A:** Being able to somehow easily obtain a digital file for a game would be useful, so I could share it with my students easily. Having a multi-player option instead of people surrounding one laptop would also be a great addition.

### Discussion

My client was satisfied with my final program. His perspective revealed some aspects of the program that could've better considered and improved upon.

**User-friendliness** was a point raised by Mr Myslov. He highlighted the fact that it would be hard for beginners to understand the rules of laser chess, which I agree on, considering that the rules and pieces are very different from regular chess. To amend this, I could add more tutorials or help dialogue, for instance, by creating a new tutorial screen containing a miniaturised board, where the user can learn how the pieces interact with the laser; although a help screen is already implemented, an interactive one would perhaps serve the purpose more efficiently. A similar approach can be applied to my custom FEN string and move notation format.

**Sharing games** was a suggestion made by Mr Myslov. Although the FEN string system allows for sharing of board positions, I realised that there is value in also sharing the entire progression of the game. This could be implemented by exporting the game to the equivalent of a chess 'PGN' file, by writing all the game information (e.g. CPU depth) to a .txt file, and then the contents of the move list.

**Multiplayer** was another improvement suggested by Mr Myslov. Admittedly, this is a big feature for a digital board game, however, I did not implement this as it was not a requested objective, and would've required restructuring my code for handling moves and the game logic. This could be achieved within Python through a peer-to-peer system, sending and parsing formatted moves either through pickling or JSON objects via HTTP methods using the `requests` module, although it would also require an overhaul of the GUI and screens to allow the option for multiplayer.

Regardless, given the limited time frame, we were both pleased with the final result.

### 5.3 Further improvements

A point not raised by Mr Myslov was the ease-of-use of the widgets. The one that I found concerning was the text input, as constantly deleting the entire FEN string, and having to manually press arrow keys to edit specific characters was tedious. I have tried to improve this by adding shortcuts such as `Ctrl+Backspace` to delete the entire contents of the text Input. To improve the text input to make it feel more familiar to standard ones, I would have to use two pointers to track the indexes of the start and end characters, for the ability to highlight and delete chunks of text. The text displayed can also be hard to read currently, especially if there are a lot of characters. This could be improved by either fixing the font width, detecting if the text width is greater than the widget width and implementing text wrapping, or allowing text scrolling.

### 5.4 Conclusion

The final product fulfilled all proposed objectives and more, and has been approved by my client.

Throughout 6 months of development, I felt that I improved on many aspects needed to be a proficient developer. Creating bespoke software allowed for conducting research, interviews, and also obtaining continuous feedback. In terms of coding, working on a large project helped in improving file management, documentation, and keeping robust backups through Git. It also gave me the opportunity to learn GLSL for my shaders, and LaTeX for my documentation. Having a greater familiarity with Pygame, I also plan to rework my widget system as a library, to be shared for the benefit of all future Pygame users.

Overall, this project was a success.
